A recently inverted uterus may be spontaneously replaced, but such a fortunate issue very rarely comes to a chronic case. The organ may be ulcerated, may be inflamed, may yield much discharge, or may bleed freely. It has been known to die and slough off, and it is natural to attribute this to constriction by the cervix, or by the lowest layer of fibres of the body, a view which seems to the practitioner to find support in the great difficulty he has in getting this lowest contracted ring dilated. But the pathology of this sloughing is surely not so simple a matter, for there is no tight constriction of any part; such constriction is to be imagined, but it has never been seen or described. The condition may find an analogy in the occasional sloughing of a polypus, whose stalk passes through the cervix; yet is not tightly constricted by it, not more constricted than it was when it was all alive, not so constricted as to arrest circulation and strangle. The difficulty alluded to, as experienced by the practitioner, is not from constriction, but from rigidity or undilatability.

These two events, removal by sloughing and spontaneous replacement, suggest the treatment in cases of chronic inversion. Formerly, the treatment by removal was regarded as the mode of cure—if that can be called cure which involves considerable danger—and, if successful, leaves the woman sterile. It is now resorted to only when artificial replacement is not successful. In some cases nothing is done, and the ulterior history of such I do not know by actual experience, but I do not doubt that they may live in a quite tolerable way, and may after the menopause become as good as cured, the displacement giving little or no trouble.

Many methods of removal have been practised. In "Martha" I have not had an opportunity of showing you the operation. There are two dangers—bleeding and peritonitis. You may pull down the uterus, holding it by volsella, attached above your proposed incision. Then you amputate by scissors, or a sweep of a bistoury. Then you arrest bleeding, if there is any. Then you use strong sutures through the peritonæum to close the opening made by the amputation. During all these proceedings you use measures to secure aseptic cleanliness.

I have said that formerly cases of chronic inversion were either let alone, or the uterus was amputated; and, if you look up old teaching regarding this disease, you will find careful statements of the number of hours, or perhaps days, between the inversion and the replacement, so great was the fear of the condition becoming chronic, and therefore regarded as incurable by replacement. Now, that is, within the last two or three decades, all this is completely changed; we regard no case, however chronic, as incurable by replacement, till experiment has shown it to be so. Replacement should be done at once—as quickly as may be—after the inversion; of such interferences we do not here speak, because the state is then very different from that of chronic inversion. It is after a case has become chronic that we now regard replacement as feasible, as the regular practice; and I am not aware that, when a case has become chronic, there is any more difficulty in replacement after the lapse of years than after the lapse of weeks or months. It is natural to suppose that peritonæal adhesions or cohesions may render replacement impossible; but I am not of this opinion. No doubt general chronic matting, or growing together, of parts may produce insuperable difficulties; but cohesions will in time disappear for the most part, and those persistent may be disjoined by the process of replacement: of this, however, I have no proof to give you.

There is nothing new in the mere replacement: that is a treatment occurring as naturally to the surgeon as reduction in a case of dislocation of a bone. The novelty is in replacement after the disease has lasted long; in the demonstration that a uterus inverted for years is as easily reduced, or nearly so, as a uterus inverted for only a few weeks; and this is the very opposite of what was taught not long ago, the opposite of what, for example, I was taught as a student by my great teacher. Many women reap the advantage

derivable from this novelty—this great change in doctrine and practice.

Some changes, or novelties, in practice are little in themselves, but great from the wideness or extent of their application and utility. Others are great in themselves as artificial anæsthesia. Others are great from the importance of the principle involved in the change. Some, like vaccination, may have a combination of greatnesses. The change in regard to inversion, is great in itself and in the principle involved; but, unlike vaccination, the change has very limited scope in practice. Inversion is rare: were it common, the change would sound loud in the ears of mankind.

Now what is this great change or novelty in principle? It is the recognition that the result is to be attained not by a strong or violent effort, not by great force, but by a small force long applied. Not great force and short time, but little force and long time. Not the driving a nail, or lifting a weight, but the bending a bow or pulling a fish by hook out of a stream. Not the rapid opening of the womb in forced delivery, but the gradual opening in natural labour. Formerly, a great effort was made by taxis, as in the reduction of a hernia, and if it failed the case was hopeless; now the taxis is tried, and if it fails the pressure is kept up till yielding comes and the difficulty is overcome.

The failure to recognise this principle of treatment was not the only error of former practitioners, they had erroneous notions of the source of the difficulty, and used erroneous practices founded on those notions. For instance, some thought the cervix was the cause of difficulty, and that, by dividing it, the reduction would be easy. But the cervix offers only trivial resistance; it dilates easily and readily, offering no strong constriction, and it is replaced without trouble. The ordinary error is to suppose that the difficulty is caused by constriction, whether in the cervix or in the part of the uterine body, near it or anywhere else. I show you here the body of the uterus amputated for chronic inversion; if you take it and try to undo the inversion you will soon be satisfied that the cervix offers no important resistance, for there is no cervix attached to it. You will also quickly satisfy yourself that constriction is not the cause of the difficulty, for there is no constriction. No cervix and no constriction, and the uterus in your hand, not deeply concealed in the woman's body, and yet reduction or undoing the inversion as difficult as ever, almost impossible. You may have a good notion of the difficulty by trying to invert an unimpregnated uterus, or an india-rubber ball resembling it. In the natural uterus there is as much constriction as in the inverted: that is, there is none, all parts being equally tight. The operation would indeed be impracticable were the tissues composing the uterine body not endowed with other qualities besides elasticity and distensibility, namely, with the quality of muscular relaxation. I believe the capability of replacement is mainly due to elasticity and distensibility, and partly to muscular relaxation, not relaxation of any constricting band, but of the whole uterine tissues. All operations founded on the idea of a special constriction are failures, being based on erroneous theory.

Now for the operation. You may first make a trial of immediate replacement. The woman, anæsthetised, is placed in the position for bimanual examination; the right hand is passed into the vagina; pressure is by it exerted on the fundus uteri, while counter pressure is maintained by the left hand on the peritonæal uterine cup through the hypogastric flap. Without the counter pressure the vagina would be undoubtedly stretched and, it may be, injured, and the right hand would pass far into the abdomen to follow the retreating or ascending uterus. The pressure on the fundus by the right hand is variously modified, this way or that, directly, obliquely, the rule generally held in mind being to replace first the highest part or that nearest the cervix, and so on. The pressure soon pushes the body within the cervix; and you may, therefore, suppose you are succeeding, when, in reality, you have not touched the real difficulty. Efforts may be continued long; even for hours. I have persevered till the woman was exhausted and I myself fatigued, and have failed, and I have also succeeded. This process may be called acute replacement, and should always be used in acute inversion, that is, when the inversion comes after delivery. At this time it should be strenuously urged till you succeed; sometimes it is very easy.

In chronic inversion the attempts at acute replacement often, indeed generally, fail, and then you resort to the new operation of chronic replacement, that is, you keep up the pressure on the fundus till the organ is worn out and yields. This may be effected in a few hours, or it may take days. Much has yet to be done to perfect this process, and it may, by the ingenuity of gynæcologists, be made easier and gentler. At first the pressure was kept up by relays of assistants, now it is done by machinery.

I show you here the instruments we have used in "Martha." Any one is like a stethescope with the ear-piece removed. The cup-like end receives the fundus uteri. At the ear-piece end are attached elastic bands, which are connected with a horizontal bandage around the body above the iliac crests. By the elastic bands the pressure is kept up. We estimated the pressure used in Mrs. C.'s case as above one and below two pounds.

The instrument causes much pain, and narcotics are required to allay it. Suddenly the woman feels the pain diminished; she may be squeamish or sick to vomiting; the elastic bands are loose; the uterus is replaced. The cup of the instrument is now lodged in the cavity of the uterine body, and so enclosed as to be with difficulty extracted. This extraction is done by the same process inverted as pushed it in, only it is done at a sitting.

After replacement of the uterus a woman readily conceives, and successfully passes through pregnancy.

Cases of partial chronic inversion by a fibroid are not very rare. I show you two from the museum. In them a fibrous polypus has, in its descent, or as it has been forced into the cervix, pulled down the uterine wall with it, making a deep depression on the peritonæal surface. In both these cases it is the fundus that is partially inverted. In one of these two, one side only of the fundus is pulled in, the uterine end of one tube dipping into the cavity while the other is in its natural site. Sometimes it has happened to be a side of the uterus that is inverted. In all such cases you are liable to be misled, not suspecting the inversion, because the push indicates the natural length of the uterine cavity, or even an exaggerated length. In all cases of separation of a fibroid from the uterus you should keep in mind the possibility of this partial inversion, lest, in cutting through the supposed attachment, you cut through the inverted portion and make a large opening into the peritonæum, an unfortunate accident which has occurred. Danger may generally be avoided by enucleating the fibroid instead of separating it by knife or ecraseur.

Naval Medical Service.—The following appointments were made on Saturday at the Admiralty:—W. H. Putsey, staff surgeon, to the Boscawen, vice Clarke; the appointment of Staff-Surgeon Trevan having been cancelled; C. E. Geoghegan, surgeon, to the Flirt; D. T. Hoskyn, surgeon, to the Shannon, vice C. E. Geoghegan; J. A. M'Adam, surgeon, to the Duncan, vice Armstrong; John Acheson, M.D., surgeon, to the Duke of Wellington.

CASES OF SPINAL DISEASE, ILLUSTRATING THE CLINICAL HISTORY OF SPINAL SCLEROSIS.

By JAS. RUSSELL, M.D., F.R.C.P.,
Physician to the Birmingham General Hospital.

(*Continued from page* 242.)

I NOW report two cases in which the spasmodic condition of the lower extremities was unquestionably of secondary formation; dependent upon prior disease, involving the entire thickness of the white matter of the cord in a limited extent. It is in the white matter of the cord that the originating lesion resides in such cases (Charcot); and the nature of the lesion, in the opinion of M. Charcot, is of a destructive character, so far as the white fibres are concerned. The motor cell, it is stated by the author I have just quoted, by its "autonomy" generally resists the invasion of the morbid process; but he quotes some interesting cases, which prove this rule to be by no means universal—cases, "perhaps, not so uncommon as is usually believed," in which the extension of the diseased process to the grey matter was proved by that change in the nutrition of the affected muscles, and in their electrical relations, which is known to attend injury to the motor cells of that portion of the cord. Dr. Gowers would assent to M. Charcot's remark, that such exceptional cases are less infrequent than is supposed, for he remarks (*op. cit.* p. 50), "It is possible that the position [of the general commencement of the morbid process on the white column] will need reconsideration, and that the degeneration in the lateral columns is sometimes, at least, secondary to, or simultaneous with, the disease in the cornua."

I may refer to an interesting observation by M. Charcot respecting the anatomical arrangement of the diseased part of the cord, when both the lateral column and the cornua are involved; an observation applicable to either of the two opinions respecting the origin of the lesion just stated. The degenerated part of the cord, he states, is usually separated from the injured grey matter by a white tract; and he infers from this arrangement that no direct extension through the agency of the connective tissue is effected, but rather through the course of the nerve fibres.

I may quote an interesting case of my own, formerly reported fully, in which, unquestionably, the extension to the grey matter took place from the lateral columns, and in which the usual consequence of the disease, reaching the anterior cornea, was very clearly exhibited in the condition of the muscles. The lower limbs had been in a state of permanent spasmodic contraction for a period of five years, dating from the commencement of the disease, and their muscular nutrition was preserved; the extension to the grey matter was attended by sudden development of very high temperature, and by constitutional irritation threatening the patient's life. The consequence was at once displayed by the muscles; their tonic contraction was at once brought to an end in one lower extremity, the reflexes were extinguished, and the muscles rigidly contracted up to that moment, hung flaccid like loose bags, and began at once to waste. At the same time there was anæsthesia over a limited area. The other lower extremity was being invaded by a similar process, of slower character, when the patient left the hospital. As the arms were at first somewhat affected also, the attack might be likened to one of acute infantile paralysis in the adult, superinduced on the other disease.

The two cases I have selected illustrate the sclerotic change, which I infer to have taken place in two different stages. In the former of the two patients, the change may be traced from its commencement; it pursues a very characteristic course; in the gradual exaltation of the irritability of the deep reflexes, concurrently with the establishing of the paralytic condition and of loss of power in the bladder, the approach towards permanent tonic contraction of the limbs may be distinctly traced. In the second patient, the sclerotic process may be supposed to have advanced further, and the condition of the lower limbs to be established, in permanent tonic contraction. In this latter case it will be remarked, that were the early period of the history, that namely of prior paralysis and anæsthesia, neglected, the phenomena would be those presented by the case of supposed primary sclerosis, just reported. In one particular the second of these two cases will be found to differ from the first, in the mode in which the rigidity came on. Whilst in the first patient exaltation of the reflexes was apparent from the first, and steadily but slowly increased in the second, according to the patient's report, paralysis had existed through two years, and in the second year was complete, before any sign of stiffness manifested itself; at the end of that time rigidity began, and was complete in six months. This observation illustrates the difference which exists among the phenomena in different cases of the class, a variation which of course must depend on corresponding varieties, in the position and character of the primary lesion. A striking peculiarity is presented by the second case in the recovery of power over the muscles of one thigh, and over the muscles moving both thighs at the hips, and yet the knee-jerk was absent in the recovered limb. The case, also, illustrates the changes which take place in the tissues around the joints of the affected limbs, when the muscular contraction has become permanent, a change by which the articular appendages become altered, in adaptation to the changed condition in which they are placed.

The progress and symptoms of the initiatory period, that of the pre-existing disease, must of course differ with the case. In the first patient, the nature of the lesion and its progress were probably clear: myelitis of limited extent, it would appear, originating in the syphilitic poison. In the second patient, the symptoms did not explain so clearly the nature of the disease, but the presence of disease, as a condition introducing the condition of sclerosis, was as distinct as in the other patient.

Limited acute myelitis, probably of syphilitic origin—Paraplegia and loss of power in the bladder—Gradual increase in irritability of the deep reflexes, tending towards permanent tonic contraction.

A. L., aged 36, was admitted February 3rd, 1880. There was nothing special to note in his family history, nor in his personal, excepting the following. He had been a man of loose habits; he had soft chancre eleven years ago, gonorrhœa seven years, and again two years ago. On a prescription from the Eye Hospital, May, 1882, was inscribed "Specific Iritis." Eighteen months ago he had a sore on his finger, and a rash appeared upon his body; at the Lock Hospital he was told that he had secondary syphilis.

Three weeks before admission, after some exposure to cold, he complained of occasional pain at the bottom of his back, and had several rigors. About January 19th, he experienced difficulty in passing urine; and on the 28th he passed urine, by voluntary effort, for the last time. On the same day (28th) his feet and ankles became weak; the lower limbs grew more and more useless during the two following days, and tactile sensibility was dull. He had acute pain in the hips and knees and upper part of the thighs when attempting to move the lower limbs, with tingling in his feet and

twitches in his legs; he describes attacks of "convulsions" in his lower limbs, after which he was unable to move his legs or his toes. There has also been some aching in the upper lumbar region. His bowels had been confined, but on two occasions, after an aperient, they had acted sharply without his consciousness.

The patient's general health does not seem to have suffered, though he has slept badly. For two days he had some aching in the fingers of either hand.

When admitted, he presented the aspect of a fairly healthy man; he lay generally on his right side with his knees flexed; he was quite unable to stand, though he could move his legs in bed, and he could not sit upright without some help. The grasp of the hands was firm, that of the left rather stronger than of the right. The use of a catheter was necessary. Tactile sensibility in the lower extremities was probably normal, excepting that ice and hot water were only recognised as moderately cold and warm. Faradic sensibility was more acute in the left than in the right leg, but in neither was there marked departure from the normal standard.

The state of the reflexes was of greater interest in connection with the patient's subsequent history. The right knee-jerk was decidedly in excess, and also the direct contraction of the right vastus; on the left side the jerk was less in excess. Marked clonos was present on the right side, to a lower degree on the left; there was slight movement in the right leg from the front tap. The superficial reflexes did not transgress the normal type; but no plantar reflex could be obtained in the right foot.

By ophthalmoscopic examination, Mr. Priestley Smith discovered traces of old iritis; the lower half of the right fundus presented a white patch, occasioned by detachment of the retina, probably of syphilitic origin. The left eye was healthy. During his residence the patient suffered from two or three attacks of ophthalmia, in which iritis was with difficulty repressed.

In the future history of the case, the symptom which attracted principal attention was the condition of the reflexes. In the middle period of the case in the hospital, their condition was affected by an intercurrent attack of inflammation, indicated by high temperature; but their steady augmentation in irritability, and the increase of tremor, were clearly marked, and the tendency to the development of tonic rigidity became very apparent.

During the first month of his residence the notes are defective; but at the end of the month it is noted that a considerable amount of tremor had made its appearance in the lower limbs, when an attempt was made to raise them, being most marked in the left leg; with this coincided very active clonos, and much muscular irritability. The superficial reflexes, on the other hand, were low. A month later (March 30th), coincidently with a sharp attack of fever with high temperature, the tremors had much increased and affected the limbs when they were at rest; the muscles of the calf did not bear the slightest traction from the foot, nor those of the thigh from the patella, without the production of active clonos. A day or two later the patient is described as crying out with flashes of pain, shooting from the feet up the leg. There was also pain in the lower part of the lumbar region, especially on moving. These pains were of temporary character. Tactile sensibility was somewhat dulled.

On April 14th, with return of rigors and high temperature, considerable rigidity was noted in each lower extremity, yet was easily overcome; tactile sensibility was more impaired; the superficial reflexes, except the plantar, continued low. The rigidity gradually lessened in the right leg, sensibility was nearly recovered in the left extremity, but remained dull in the right. When the last note was made on June 9th, before the patient left the hospital at the end of July—the temperature having settled down to normal during the preceding month—both lower limbs were rigid, and the feet inverted; clonos was produced with still greater facility, even by flipping the skin; motor power remained, just sufficiently to render the patient able to flex and extend the limbs in bed. Five months later the patient called at the hospital; he could just succeed in raising his legs from the bed. Muscular nutrition of lower extremities was perfect; but the least attempt at passive motion, or handling the limbs, caused complete rigidity in extension, easily overcome. There was active knee-jerk. Tactile sensibility was impaired in one limb, normal in the opposite. It was observed that reflex action was preternaturally active in both arms, on tapping the flexor tendons or the radius. The urine was passed involuntarily. The catheter had been required during the entire period of hospital residence, and much trouble had been produced by cystitis, which rendered constant washing of the bladder necessary.

Treatment, which was vigorously directed towards the supposed syphilitic element in the case, proved entirely fruitless, and therefore need not be described. At one time the patient's health failed considerably, but on the occasion of his last visit he was in good bodily condition.

Gradual access of paralysis through one year; then sudden increase with anæsthesia—Commencement of rigidity at the end of the second year.

W. S., aged 33, a brewer, was admitted into the Birmingham General Hospital on September 7th, 1883. His disease, which was of three years' duration, commenced with pain at the back of the head, and in the muscles at the upper part of the back; his sight, too, was confused. The pain in the head was often severe. During the same time his walking became impaired. One day, especially in damp weather, he could hardly drag one leg before the other; on another day he walked quite well; often he had to keep his bed for two days, on account of languor and want of power in his lower extremities. About the end of the first year of his illness he had been ailing on one particular day, when he was seized in the evening with pain and a sense of weight at the bottom of the abdomen, which drew him down; the pain lasted only for that evening. On the following morning he left his bed, and went into another room, but in the evening he could not return without assistance, and he has never walked since. His legs were not stiff; they were perfectly loose, and "could be put anywhere," but "he could do nothing with them." At the same time he entirely lost sensation in his lower extremities and in the lower part of the abdomen; a pin could be thrust into his legs without his knowing it, and his leg has been hanging out of bed "unawares to himself!" In a month sensation began to return, and gradually became normal. He has never had much pain. There was only temporary and slight trouble with his bladder.

The stiffness has been coming on for twelve months, and has been complete for six months. He is positive that during the whole second year of his illness the limbs, though paralysed, were perfectly lax. The right knee has escaped the stiffness altogether, though both lower extremities had been affected with paralysis, but the right thigh had partially regained power. He had only slight tremor. He lost flesh during the first year of his illness, and when the complete paralysis came on, he only weighed ten stones; he has recovered two stones during the last nine months.

He had a "small pock" on the penis nine years ago, two days after blotches came over him, but they lasted only two or three days. He has had no other venereal

affection. He indulged freely in intercourse at an early age, and at present is subject to nocturnal emissions. He does not have erections. He admits hard drinking of ale and spirits for five years, up to two years ago. His liver is healthy, apparently; his urine is free from albumen.

The patient looks in excellent health; muscular nutrition is perfect. The right knee-joint is perfectly mobile, and can be freely moved by the patient himself, as also can both limbs at the hip-joint. The left lower extremity, and the right at the ankle joint, are in tonic rigidity, the feet being inverted; the tarso-metatarsal joint is strongly bent, hollowing the sole of the foot, and the toes are rigidly flexed.

As regards the reflexes, the only point which requires notice is the entire absence of the knee-jerk on the right side, although the muscles are free from spasmodic contraction and obey the will with a certain power; nor does any spasmodic movement follow the tap on the muscles of that limb. There is no clonos, and no tremor; no cremaster and very slight plantar reflex; the abdominal reflex is active. Tactile sensibility is normal. The only urinary trouble is that the "water comes too quickly." I omitted to examine the eyes with the ophthalmoscope, but Dr. Bond found the discs healthy.

The patient left the hospital unrelieved. The chief treatment consisted of scoring the back with the hot iron, the use of iodide of potassium, afterwards of belladonna and atropine. It is to be noticed, that although the atropine produced its full physiological effects, no relaxations took place in the state of spasm in the lower extremities; and that when under the influence of chloroform, none but questionable diminution of the contraction took place. Whilst in the state of unconsciousness, Dr. Bond found the ankles and the joints of the feet fixed, either by changed condition of the ligaments, or by adhesion, or by both. The left knee was so firmly fixed, that it was impossible to rupture the retaining agent without the employment of an unjustifiable amount of force. The operation of forcible extension, in the case of the ankles, was not followed by any beneficial result, and some swelling, with a good deal of pain, remained for some days.

(*To be continued.*)

NOTE ON THE TREATMENT OF ENTERIC FEVER BY THE EXTERNAL APPLICATION OF COLD.

By DAVID W. FINLAY, B.A., M.D., M.R.C.P.,
Assistant Physician to the Middlesex Hospital.

One of the most important points brought forward in the discussion on this subject, at the meetings of the Medical Society, is the fact that, under the antipyretic treatment, the proportion of deaths from intestinal lesions has increased; and if this could be held to be due to the bath, it would go far to discourage its use. There is no good reason, however, to suppose that the two things stand to each other in the relation of cause and effect; the true explanation is rather to be looked for in the varying character and severity of particular epidemics. Of the cases which I have lately had charge of, three have died—all of perforation; and all have been treated on the plan lately under discussion.

But in order to appreciate the significance of this, it is necessary to know something about the cases themselves. The following brief notes will be helpful in this direction. The first was a female, aged 30, who had been ill a fortnight before admission, and had had a good deal of diarrhœa. On the evening of the day of admission, she had a temperature of 104·6°, at which the bath was employed. This was the only bath she had, cold sponging being afterwards substituted. Her diarrhœa continued during her stay in the hospital, and perforation took place on the twenty-second day of the fever, the last sponging having been on the seventeenth.

The second case was that of a man, 24 years of age, who had just passed through an attack of acute rheumatism and enteric fever combined, and died on the eleventh day of a relapse of his enteric fever. He was bathed when his temperature was 103·8°, on the fourth day of his relapse, the bath being followed by compresses on the chest and abdomen. Next day he had a second bath, when his temperature was 103°, and again compresses. Two days later, he had a third bath and compresses as before. This was the last bath he had, and he died of perforation four days later.

The third case was a female, 21 years of age, who had had abdominal pains and diarrhœa for ten days before admission. She had three baths in all, her average temperature being 103° when bathed. She perforated on the fourth day of her stay in the hospital, having had persistent diarrhœa from the time of her admission.

Now the first and third cases had been long ill with severe attacks before coming under treatment, and the other had been depressed by his primary attack, complicated, as it was, by acute rheumatism; so that looking to the circumstances of each case, I should say, not that perforation took place in consequence of antipyretic treatment, but in spite of it.

And I think we should expect that a high degree of pyrexia, or long continued pyrexia, would *favour* perforation, looking to the effect which it has in causing degeneration of muscular structure.

We know that the heart suffers from this degeneration, hence pulmonary congestion.

We know that the external muscles of the body also suffer, and I have had under my care a case in which, during an effort by a delirious patient to get out of bed, the rectus abdominis on each side was ruptured.

The same degeneration must affect the muscular coat of the intestines, leading to distension of the bowels, and accumulation of fæcal matter, which are just the conditions likely to end in rupture.

From this, it would follow, that the best way to guard against perforation is to keep down the temperature.

Almost all are agreed as to the dangers arising from a high degree or long continuance of pyrexia in enteric fever; and as to the power possessed by the cold bath of reducing this pyrexia; and if the moderating of temperature be good in itself, it may be asked, what have we to set against it on the other side of the account?

On this point we look in vain for anything definite or conclusive. We have facts in abundance on the one side, nothing but theory on the other.

New Test for Pus in the Urine.—A few drops of hydrogen peroxide brought into contact with pus will produce an effervescence similar to that caused by hydrochloric acid on a carbonate. The action continues until all the pus is destroyed, so that it cannot be recognised microscopically. It affords the simplest and most delicate test for pus in the urine, the smallest quantity being easily detected.—*New York Medical Record*, January 19th.

REMARKS ON SIR W. G. HUNTER'S REPORT ON THE CHOLERA IN EGYPT.*

By Surgeon-General J. MURRAY.

Dr. Hunter considers cholera an endemic disease, arising in the locality of Damietta in the same manner as it arises in Bengal, which is called the cradle of the disease. I consider that the characteristic of an endemic disease, such as ague, is, that it is produced in a certain locality; but is not communicable from the sick to the healthy out of that locality—therefore, if cholera may be so communicated, it is not, in my opinion, an endemic disease. The frequency of its appearance in Bengal is an undoubted fact, but it does not appear so constantly as small-pox, which is a typical epidemic disease, transmissible through the clothes of the sick, as well as by inoculation, and certainly more frequently by personal contact than cholera. Frequency of occurrence no more constitutes a claim for this disease to be classed as endemic than the constant appearance of small-pox in Bengal or venereal disease in London would class them as endemic diseases. The practical objection to this misnomer is, that those who use it are supposed to imply that in their opinion it is not communicable.

Cholera has the same symptoms and character, whether arising in the damp climate of Bengal, the hot and dry climate of central India and Scinde, or the cold frozen climate of Russia. It progresses from hot to cold countries, and *vice versâ* from cold to hot ones, across thousands of miles of land and water, and yet some writers call it an endemic disease, or an endemic disease assuming a new form. It is misleading to call the different stages of the same disease by the names of separate diseases. The physician who is unable to diagnose cholera till it has reached the stage of collapse and suppression of urine will lose the best opportunity of saving life, whilst the body is still amenable to the action of remedies. The hospital physician who admits cholera patients promiscuously into a general hospital, subjects the other patients to great danger. Out of the fourteen cases that occurred at Ramleh during this Egyptian epidemic, eleven occurred in patients already in hospital for other diseases. In quoting the immunity of the inmates of hospitals, it is the practice to illustrate the point by tabulating the immunity of hospital attendants, without alluding to hospital patients. The history of the disease at Ramleh, in this Egyptian epidemic, is an illustration of what is not uncommon in India. The propriety of changing the name of the disease in the hospital register, under which the patient has been admitted, is not always attended to, when another disease supervenes which proves fatal. I was under the impression that the question of communicability had been settled, in the opinion of the profession in India, by the history of the Hurdwar epidemic of 1867, when nearly three millions of pilgrims were assembled, and cholera broke out on the 12th of April, and followed their progress homewards for 500 miles; appearing simultaneously with their arrival in the various towns and villages, and spreading over the districts. Under instructions from Government, I called for the opinions of the Medical Officers of H.M.'s and the Indian services, amongst other points, on the communicability of cholera. Replies were furnished by 505, of whom 478 answered in the affirmative—Yes; five answered in the negative—No; and 22 were doubtful. As to the different channels through which the disease was transmitted, viz.:—i. from the person; ii. from place; iii. by atmosphere; iv. by water; v. through evacuations, there was a slight difference of opinion in reference to personal contact, but on the five questions, out of 2,525 opinions, 2,113 were "yes," 90 "no," and 322 doubtful. The Hurdwar epidemic of 1879 was a literal repetition of that of 1867, the only difference being that the number of pilgrims was a little under one million, instead of being nearly three, as on the previous occasion; and that the districts were affected a few days earlier where railways had been introduced, by which the pilgrims were conveyed more rapidly, the reports being the same that the first cases were pilgrims. I was in hopes this corroborative evidence would have convinced the doubting, and more mature judgment corrected the negative views; but in this I am disappointed. Dr. Brydon's opinion that the simultaneous appearance of the cholera, and the arrival of the pilgrims in 1867, was merely a coincidence with the arrival of his ærial epidemic atmosphere, or Dr. Cuningham's suggestion that the pilgrims in 1879 being very tired and weak, were affected by the villages and and not the villages by them, do not rest on any solid foundation. I do not understand this ærial epidemic influence any more than the production of the disease at Damietta by spontaneous generation mentioned by Dr. Hunter. The explanation perhaps would be more comprehensible if he would inform us whether he considers that the cholera germ or lower vitality was at once produced in its full virulent power, or if, like other vitalities, it was gradually developed from some milder or more primitive form as is now generally supposed to be the usual course.

The search for the germ by the microscope is very interesting, though its non-detection would merely be negative evidence. The hope of producing a milder form of the disease by cultivation, which might protect from cholera, loses much of its importance from the fact that vaccination does not afford a *more* effectual protection from small-pox than a previous attack of small-pox itself, and that one attack of cholera affords no appreciable protection from a second or third attack, as was shown by the returns of the Central Prison at Agra during four epidemics in the successive years 1860–61–62–63, when the history of 800 cases was carefully investigated. More extended knowledge of the disease will probably explain many of the cases which are now called of spontaneous origin; particularly a knowledge of the period during which the germ may remain dormant, inside or outside the body, and then be endued with activity by surrounding circumstances, and what constitutes these circumstances? Our experience of the dormant period *in the body* shows that in some instances it does not exceed a few minutes, while in others it extends to hours or days; it rarely exceeds three or four days, but occasionally it continues in the stage of diarrhœa one or two weeks. Personal experience may influence my attaching too much importance to the rapid action of the poison, which I have myself felt and have witnessed in others.

[I may here mention a few instances which strongly impressed me at the time, on which each may form his own opinion. On one occasion, in 1856, when inspecting the hospital of the Central Gaol at Agra, during a very severe epidemic, I saw a row of fourteen dead bodies arranged in the dead house, and then entered the cholera ward. When there I was affected by a sudden shock in the epigastric region, which was immediately followed by a deadening sensation which rapidly extended over the body to the extremities. To avoid alarm or panic amongst the hospital attendants, I asked the native doctor if he had a good supply of quinine in stock and to show it me. As I walked through the hospital the dead feeling extended all over my body. I had forgotten that I had ordered the native doctor to show me the quinine, but he did so and said,

* Delivered at the Epidemiological Society, on January 9th, 1884.

"Look, sahib, there is plenty." I took a large quantity in my hand and put it in my mouth; it had no more taste than chalk. I entered my carriage and told the coachman to drive home, and I continued to chew the quinine. Gradually it began to taste bitter, and a sense of warmth appeared in the stomach, which gradually extended, and I was feeling comfortable when I reached home, and took two cholera pills and lay down. I soon fell asleep, and awoke free from uneasiness and danger. On another occasion, in 1861, on inspecting the European hospitals, I saw the clergyman speaking to a cholera patient in the Artillery Hospital. He suddenly went to the verandah and was violently sick, vomiting a watery fluid. I immediately gave him a couple of cholera pills, and took him home and put him to bed, where he soon fell asleep, and had no further signs of disease. On the same morning, when inspecting the hospital of the European regiment, I saw the officer of the day, who was visiting the hospital, vomiting in the verandah, and he was attended to by the surgeon of the regiment. In this case the disease advanced to the stage of collapse, and proved fatal in a few hours. On the same day, the officer commanding the artillery and two of the carrying party attending the funeral of one of the artillery-men were attacked with cholera during the day, and the company-officer and one of the men died, the former during the day, the latter on the following. On another occasion, in 1856, Dr. Farquhar accompanied me to the hospital of the Central Prison, and half-an-hour after we left, he was attacked with vomiting during our visit to the Thompson Hospital, and he immediately took two cholera pills, and we drove home, when he lay down and soon fell asleep, and awoke well. On another occasion, at Indore, in 1848, after seeing a number of cholera cases from the bazaar, at the door of the jail hospital, I went home, and after breakfast, I was suddenly seized with profuse watery purging. I immediately took two cholera pills and lay down, and soon fell asleep. I had no more looseness, and only light-coloured evacuations for one or two days.]

The period during which the germ may remain dormant, but viable *outside the body*, is various. In water it is very short, the disease coming into action on the following day, where water was the channel of communication, as at Jogh Kelan, in the Punjaub, and at Moradabad, during the epidemic of 1867. The addition of water to the dormant germs in dry soil acts with similar rapidity in rousing it into activity, as seen in the action of the cyclone wave in Bengal, in 1875 and 1879, and this coincidence, if nothing further, is recorded in numerous instances after a fall of rain at the commencement of the rainy season, or after heavy showers on other occasions. This would afford a simple explanation of many of the instances recorded as of spontaneous generation in Bengal and other parts of India, where the germ may have been deposited the previous year, or perhaps at an older date. Several years are indicated in some cases, as when the workmen were attacked immediately on opening the grave of some road-makers, who had died of cholera four years previously.

The outbreak of severe attacks of cholera at large assemblies of people at fairs and marriages, is of frequent occurrence in India. The first on record was at Hurdwar, in 1785, where it is stated that 20,000 died in one day. There was a slight attack at the Koom-ke-Mela, in 1855, and very severe attacks in 1867 and 1879. There were severe attacks at Mahadeo, in 1861 and 1865, and at Allahabad, in 1880. The records of outbreaks at fairs all over India, are innumerable; taking place in some instances in districts where the disease has been some time prevalent in a mild form, and in others where the disease had been in a severe form in the previous year. It is not always practicable to trace the spark that fires the magazine. We may imagine that the unsanitary state of the ground stimulates the germ dormant in the soil. I see no necessity for imagining a spontaneous origin of the disease at these fairs. Of the various agencies that appear to excite the dormant stage of the germ when outside the body, water is one of the most general and powerful. Outbreaks after a fall of rain are frequently recorded, especially at the beginning of the rainy season. The attack at Hurdwar, in 1867, on the 12th April, had been preceded by a heavy fall of rain on the 11th.

The connection of *season* with the course of the disease is so intimate as to preclude the probability of its being merely a coincidence. The disease, during the cold season, is so rarely seen as to be considered dormant all over India, with the exception of Lower Bengal and some parts of the Madras coast, which are subject to cyclone waves. That it is not temperature alone that causes this intermission is evident from the history of the disease in Europe, where it has raged at far lower temperatures than exist in the cold season in India. Neither is it moisture alone which facilitates its action, as the climate is dry in the Upper Provinces and the Punjaub in the month of April when the Hurdwar epidemics of 1867 and 1879 prevailed; neither is it high temperature alone, as this is wanting in Europe, especially in Russia. The unsanitary state which I have supposed capable of developing (not creating) the cholera germ is, unquestionably, a powerful auxiliary in promoting the progress of the disease to the more advanced and dangerous stages, and in diminishing the power of the body in throwing off or mitigating the disease. The efficiency of the precautionary measures to be adopted on the approach of an epidemic in the isolation of the sick and removal from a tainted locality, will depend on their accordance with these views.

CARBOLIC ACID POISONING IN A CHILD—RECOVERY.

By F. HEWITT OLIVER, Maidstone.

David G. W., aged two years, was brought to me at 1.30 a.m. on December 11th, 1883, by his father and mother, the father stating that ten minutes previously he gave the child from a cup, carbolic acid in mistake for cold tea. Immediately the child had swallowed it he cried out and complained of pain about his mouth, throat, and stomach; the father then discovered his mistake, and immediately brought him to me.

1.30 a.m.—(Ten minutes after taking the poison.) The child is quite senseless, with contracted pupils not responding to light, insensible conjunctivæ, muscles over the whole body relaxed; he is discharging a good deal of frothy mucus from the mouth, about the angles of which there is slight corrosion. The whole body is cold, the temperature being 94·8°. I immediately poured some three or four ounces of olive oil down his throat, most of which he swallowed; gave him an emetic of sulphate of zinc, and administered ten minims of ether hypodermically.

1.45 a.m.—The emetic has not acted; brandy ʒij given, diluted with olive oil.

2 a.m.—Pupils and conjunctivæ unaltered, pulse clearly perceptible, surface of body cold and clammy; temperature 95·6°, respirations 35 in the minute, and stertorous.

3 a.m.—For the last hour there has been no change.

3.15 a.m.—Respirations 36 and irregular; for a few moments slow and laboured, then rapid and shallow. Pulse 130 and irregular, brandy ʒij repeated, after which he opened his eyes and cried lustily, then dropped back exhausted and senseless; the feet, hands, and face are colder; friction applied.

3.30 a.m.—A decided improvement; he has opened his eyes and looked round, conjunctivæ are sensitive respirations 36 and laboured, external strabismus of right eye, pulse 92 and fuller. Temperature 96°. The child cries lustily.

4 a.m.—Respirations 37. He vomited matter smelling faintly of the acid.

4.15 a.m.—Respirations 40. Pupils and conjunctivæ again senseless. Pulse 120, feeble and intermittent. The corrosions about mouth and tongue are now well marked. He again vomited, the ejecta smelling strongly of the acid, and containing brown streaks. Brandy ʒij repeated.

4.30 a.m.—Breathing still hurried and laboured, but quieter; he frequently cries out, sits up, and opens his eyes, pupils now respond feebly. Pulse fuller and regular.

I now ordered his removal home, with instructions to his parents to wrap him in warm blankets, with hot water bottles to his hands and feet, and to give him nothing but milk and brandy.

9 a.m.—He has slept a good deal, and is in a warm glow; there are symptoms of laryngitis, the breathing is hurried and sometimes laborious, and the face blanched. He takes brandy and milk well.

December 12th, 9 a.m.—Cough very troublesome; cries out and complains of pain about throat, thorax, and epigastrium; does not take nourishment so well.

2 p.m.—Inflammation is extending to bronchial tubes of both lungs.

December 13th, 11 a.m.—A fair night, taking nourishment well, and breathing a little easier.

After this he went through a smart attack of bronchitis, from which, under appropriate treatment, he gradually recovered, and at the present time (January 10th, 1884) is running about playing with other children, and is, in fact, quite himself again.

The child appears to have swallowed at least half an ounce of McDougall's "Patent Sewage Carbolic Acid," which I understand is a "crude acid containing about 30 per cent. carbolic acid, the remainder being tar oils." I am not aware of any case on record in which so large a dose was taken without a fatal result.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. THOMAS'S HOSPITAL.

CASES OF STRANGULATED HERNIA—OPERATION—ATTEMPT AT A RADICAL CURE—WITH REMARKS.

By BERNARD PITTS, M.C., F.R.C.S.,
Assistant Surgeon to the Hospital.

Case I.

Henry S., aged 37, bricklayer, was admitted to St. Thomas's Hospital, February 24th, 1879, with a strangulated right inguinal hernia, of about the size of a duck's egg. The patient stated that he had had a rupture for twenty years, but never worn a truss. For several years he had been unable to reduce the whole of the swelling.

The symptoms of strangulation commenced on the 22nd, and pain, vomiting, and obstruction of the bowels had been continuous since. Failing with taxis to make any alteration in the hernia, I cut down on, and opened the sac. A large mass of matted omentum was found, and behind this was a small knuckle of dark intestine. Having separated some adhesions, the gut was returned, and the omentum removed after tying the pedicle with a silk ligature. The sac was then dissected up, and the greater portion cut away. The cut edges of the remaining portion, or neck, of the sac were then inverted, and the opening closed by means of catgut sutures. The external wound was then brought together with silk sutures, a drain being provided at its lower part.

The operation was performed with antiseptic precautions. The man recovered rapidly, and left the hospital in three weeks' time, wearing a truss.

This patient was examined on February 25th, 1884, five years after the operation. He had been engaged ever since in very heavy manual labour as a bricklayer, but had always worn a truss whilst at work. There was a small bubonocele perceptible when he coughed. The hernia had, however, never once descended into the scrotal region, and has not given him the slightest pain or discomfort. There has been no increase in the size of the swelling for the last three or four years.

Case II.

William M., aged 16, was admitted to Edward Ward on October 13th, 1877, with strangulated right inguinal hernia. He had suffered from hernia since childhood, but had never worn a truss. On the evening of October 12th, the rupture which is constantly in the scrotum, became enlarged and painful. Sickness at once commenced.

On examination the hernia was found to be of large size, of cylindrical shape, tender, and without impulse. I tried taxis under an anæsthetic, but was obliged to open the sac. A coil of much congested intestine was returned, and a large piece of omentum removed. The testicle was at the back of the sac, but of nearly normal size. A drainage tube was introduced, and the wound closed by wire sutures, and dry lint applied as a dressing. Convalescence was retarded by a sharp attack of orchitis; but the boy left the hospital on November 27th quite well, and wearing a truss.

This patient was again admitted into the hospital under my care on the evening of December 27th, 1880, with strangulated inguinal hernia of the same side.

After the last operation the hernia reappeared, fourteen days subsequent to leaving the hospital. He managed, however, to keep it well under control for about a year with his truss, but afterwards the hernia generally came down whenever he took the truss off. A few hours before admission the hernia came down a little larger than usual, whilst walking with his truss on. Pain and sickness directly ensued, and he came to the hospital.

On examination a tense hernia, of cylindrical shape, was seen in the right inguinal region. The testicle could be felt below the swelling. The patient was suffering a good deal of pain, and was frequently sick. Ice was applied for two hours without any relief. So taxis under anæsthetic was attempted. I was compelled, however, to make an incision through the old cicatrix, and found a constricting band in the upper third of the inguinal canal. The sac was opened, and the congested bowel returned, and some adherent omentum removed. The testicle was separated by adhesion from the hernial sac. I now removed the sac, tying the neck of it with stout catgut. The old cicatrix was then excised, and parts brought together with silk sutures, a drainage tube being placed at the lower part of the

wound. The operation was done with antiseptic precautions. The wound healed without any trouble, and he left the hospital on January 24th, wearing a truss.

He has been under observation since, and was last seen February 12th, 1884. The hernia has never reappeared; there is only a very slight impulse on coughing opposite the internal ring. The inguinal canal is closed, and does not permit the introduction of the finger. Since his operation he has been constantly engaged in heavy lifting work, and he continues to wear a light truss.

Case III.

Alfred Cozens, aged fourteen months, was admitted to Victoria Ward, on September 12th, 1881, with right inguinal hernia strangulated. A tense swelling was found in his scrotum, of the size of a hen's egg. The mother had been unable for the last 30 hours to reduce the hernia; before this she had had no difficulty in the reduction. Having failed by hot bath and manipulation under chloroform to return the bowel, I operated, and on opening the sac found the cæcum, which, however, was not adherent. After freeing a constriction at the neck of the sac, the bowel was readily returned into the abdominal cavity. I then dissected away a portion of the sac, and closed its mouth with catgut. The sides of the inguinal canal were brought together by silk sutures. The wound healed slowly, but the child left the hospital quite well at the end of six weeks. I last saw the patient in October, 1883—two years after the operation. There was not the slightest sign of any return, and the inguinal canal remained quite closed. A light truss, at my request, had been worn, but permission was now given to the mother to discontinue it, for we considered that the hernia was absolutely cured. The mother expressed great thankfulness that the strangulation had occurred, for before that event she was constantly engaged in reducing the swelling, and had great trouble in getting any truss to act efficiently.

Case IV.

Charles E., aged nineteen, engineer, admitted to St. Thomas's Hospital, June 17th, 1883, with right inguinal hernia strangulated. A swelling in the groin was first noticed five years ago, it gradually increased in size, but always disappeared on lying down. The symptoms of strangulation commenced early on the morning of admission, and he was brought to the hospital about five in the afternoon. He was then much collapsed with pain. The tumour was pear-shaped, and occupied the right side of the scrotum. An ice-bag was applied, and subcutaneous injection of morphia given. After a short trial of the application of ice, taxis under anæsthetic was attempted, and, failing to reduce the hernia, I operated, and after opening the sac, and relieving a constriction at its neck, I returned the bowel into the abdominal cavity and removed some omentum, placing a ligature on it as high as possible. The testicle was found in the hernial sac, and was normal in appearance. The hernia was, therefore, of the congenital form. The sac was removed in part, and its neck ligatured with stout catgut. Catgut sutures were also employed to bring the sides of the inguinal canal together; a drainage tube was introduced, and the external wound closed with silk sutures.

Antiseptic dressings were applied. The patient made a good recovery, but had a rise of temperature for a few days, due to orchitis, and suppuration requiring a counter opening at the bottom of the scrotum.

He left the hospital on July 18th well, and wearing a truss. He has been under observation now for eight months, and there is no sign of any recurrence of the hernia. The finger cannot be introduced into the inguinal canal, which is closed by adhesive inflammation.

Case V.

William P., aged 45, baker, was admitted to St. Thomas's Hospital on August 20th, 1881, with a large femoral hernia, irreducible, and apparently strangulated.

He had had a hernia for fifteen years, and for the last eight years it had remained irreducible, and of about the same size, namely, rather larger than his head.

On August 22nd, I was compelled, by the symptoms, to operate, and had to open the sac. The contents consisted of the cæcum, with several feet of small intestine, and a large quantity of omentum. I removed the omentum, returned the small bowel, and then separated the adhesions of the cæcum, and ascending colon to the sac, and returned this part of the intestine also.

The sac was next dissected away; the portion of sac removed measured 26 inches in circumference, and was very thick, and cartilaginous in places. A number of stout catgut sutures were then passed through the cut edges of the neck of the sac, and the abdominal cavity thus shut off. All redundant skin was also removed, and parts brought together by silk sutures. The man made a good recovery. This case is recorded at length in Volume XI. of the St. Thomas's Hospital Reports. I have briefly referred to it in order to mention the present condition.

He has worn a truss with large pad ever since whilst at work, and has remained free from his old burden of a large irreducible hernia. With the truss on, no swelling is perceptible; but on removing the truss, and coughing, a swelling of the size of a large egg makes its appearance at the upper part of the cicatrix. His present condition may, therefore, be considered as very satisfactory. This patient was last seen on February 16th, 1884, nearly three years after the operation.

Case VI.

Frances V., aged 46, laundry-woman, was admitted on the evening of August 30th, 1882, to St. Thomas's Hospital, with the following history:—She had suffered from right femoral hernia for twenty years, and on August 30th, 1880, was operated on at Guy's Hospital for strangulation of the same. The hernia was then about the size of two fists. A year afterwards the increasing size of the hernia rendered her truss useless, and it became as large as a child's head, but was always reducible. On December 4th, 1882, during a violent fit of sneezing, the coverings suddenly gave way, and about a foot of intestine escaped through the rent. For this condition of things she was brought to St. Thomas's Hospital. After returning the prolapsed bowel—and the intestine that still remained in the sac—I proceeded to attempt a radical cure, by dissecting away, and removing the thickened sac, and bringing the cut edges of the neck of the sac into approximation by catgut sutures, and then removing all redundant skin. She left the hospital early in January, 1883. I last saw the woman on the 7th of February, 1884—fourteen months after the operation. By the aid of a truss she had been able to keep the hernia completely under control. When the truss is removed, and the patient stands up and coughs, a swelling appears beneath Poupart's ligament nearly as large as a child's fist. There has been no increase in this reappearance during the last few months. She has thus got rid of an immense burden.

This case was read before the Medical Society last year.

Case VII.

Clara F., aged 54, was admitted to St. Thomas's Hospital, July 5th, 1881, with right femoral hernia strangulated. The symptoms had existed three days.

She had been subject to right femoral hernia for four years, and left femoral for twelve years.

On examination a tense swelling of the size of a hen's egg was found in the right groin; the abdomen was distended and tender, and the patient much collapsed. I operated immediately, without attempting taxis, and on opening the sac a small very dark knuckle of intestine was found, and reduced after division of a constriction at the neck of the sac. A portion of omentum was removed, and a considerable quantity of fluid escaped from the peritonæal cavity.

In this case the sac was removed, but I did not place any ligature around its neck. A drainage tube was introduced into the abdominal cavity, and antiseptic dressings applied. The drainage was removed at the first dressing, and the patient made a satisfactory recovery, and left the hospital on August 8th, wearing a truss.

I saw her for the first time afterwards on February 27th, 1884, about two years and a half after the operation, and found to my surprise that the hernia had not only never made its appearance again, but I could not discover the slightest impulse when the patient was standing up and coughing. The left femoral hernia was in much the same condition as when she was in the hospital. This woman had continued to wear a truss according to advice; she had not been leading a very active life, but had suffered for years from a very troublesome cough. She was recommended to still continue wearing a light double truss.

Remarks.—These cases came under my care, for the most part, whilst Resident Assistant-Surgeon at St. Thomas's Hospital, and I am indebted to the surgeons for their kindness in allowing me to take charge of them.

They represent those cases of strangulated hernia, where an attempt at a radical cure was made, and where one has been able to note the after-condition of the patients.

I have ventured to record them, in order to show what a very considerable advantage is obtained by endeavouring, when operating for the relief of strangulation, to place the patient in the best possible condition for after-comfort. The incision for the relief of a constriction, necessarily tends to enlarge the aperture, and often, as a result of this unavoidable weakening of the abdominal wall, the hernia tends to increase greatly in size.

There can be, however, very little doubt, that without much increased risk, this tendency can be overcome, and the patient placed on recovery even in a better state as regards liability to further protrusion, than before the strangulation occurred. A sufficient time, varying from five years to one year, has elapsed since these cases were operated on, to enable one to form an estimate of the advantage gained, and I have no hesitation in stating that they are all in a far more satisfactory condition, than if one had been contented with doing, what was merely absolutely necessary to relieve immediate symptoms. This is more especially shown by cases 2 and 6, for both these had been the subjects of a previous operation for strangulated bowel, and in both the hernial protusion increased in size very shortly afterwards. Since the second operation for strangulation (which was combined with radical cure), number 2 has had no return of his hernia, although more than three years have elapsed, and number 6, instead of the very large protusion which followed the first operation, has been placed by the second in a condition of comparative comfort.

Much depends on the nature of the case, and the degree of strangulation, as to whether the abdominal cavity may be completely shut off, or the operation prolonged by an attempt at a radical cure. In old people I have always been contented with simply relieving the strangulation. When the recovery of the intestine is doubtful, as in Case 7, it would be highly dangerous to close the mouth of the sac; but the sac itself may be safely removed, or a portion of it, near its neck excised. This proceeding hardly involves any increased shock, or lengthening of the operation, and decreases the liability to recurrence considerably. Case 7 affords a good example of the advantage thus derived.

In dealing, however, with very large herniæ, as in Cases 5 and 6, the closure of the mouth of the sac is not only an additional security against protrusion, but the shutting off in this way of the abdominal cavity, must have an important influence on the chance of recovery. The rapid adhesion of the peritonæal surfaces to one another, prevents, in a great measure, the possibility of any septic process gaining access to the peritonæal cavity.

In femoral herniæ of large size, whatever relief may be afforded by removing the sac, the crural opening must remain dilated. In Cases 5 and 6, at the time of operation, three fingers could easily be passed through the ring into the abdominal cavity.

An inguinal hernia naturally gives the best chance of a satisfactory result, for one is able, besides removing the sac, and closing its mouth, to bring the sides of the canal together, as for example in Cases 3 and 4.

In Case 2 no sutures were used for the inguinal canal, and yet the result is a good one, and proves that much may be gained by merely removing the sac. In operating on a similar case, I would, however, now employ sutures for the internal ring and canal.

When the hernia is of the congenital form, as in Case 4, of course a partial removal of the sac is alone possible, and special care is required not to injure the cord.

The question naturally presents itself—What is the best course to adopt, when strangulation has been relieved by an extra-peritonæal operation? The removal of the sac, or at any rate a wide ring of it, seems so essential for a radical cure, and the increased risk (with antiseptic precautions) so small, that in a young, healthy subject, it would appear quite a justifiable measure to adopt. Supposing, however, that one is dealing with a very large hernia, as in Case 5, then the increased risk to life, would, I believe negative the attempt. I should certainly have felt quite satisfied with relieving the constriction; the sac, however, having been of necessity opened, I felt bound to do the best I could, to rid the man of his burden, although the operation was in this case, in consequence, greatly prolonged.

I have not had the opportunity for attempting a radical cure in any case of strangulated umbilical hernia, but probably in certain cases such an attempt would be desirable.

How long should an apparently successful case of radical cure wear a truss? Although much tempted in several of the cases to allow the patient to leave off the truss, I feel that the risk of recurrence is too great to run, more especially as they have all been in serious danger once, and in two instances, twice, from strangulation. The child alone has been granted this indulgence. It would be desirable that those who have had larger experience in this or other forms of radical cure should give the profession the benefit of the later results of their cases.

The Dorpat University.—In January of this year, the total number of students at Dorpat was 1,530, and of this exactly one half (765) belonged to the medical faculty, viz.:—652 medical, and 113 pharmaceutical students. Then follow the juridical faculty with 265 students, the theological faculty with 202, the historico-philological faculty with 184, and the physico-mathematical faculty with 114 students.—*St. Petersburger Medicinische Wochenschrift*, February 9th.

Medical Times and Gazette.

SATURDAY, MARCH 1, 1884.

Politics and party fights have so absorbed Parliament, that very little of special interest to medical men has occurred during the week; but the appointment of a Royal Commission to enquire into the housing of the working classes, will have been hailed with great satisfaction by the profession at large. No body of men are better acquainted than are medical men with the deplorably bad condition of the vast majority of the houses inhabited by the working classes, and with the frightful overcrowding of even the worst of these houses; and none can so well and fully appreciate the extent and gravity of the evils caused by such conditions. We have often dwelt, in these pages, on the physical and moral deterioration inevitably consequent on overcrowding, in even fairly well-built and provided dwellings; and have pointed out that those evils are enormously intensified when, as is so generally the case, those dwellings are badly built, are without proper drainage and sewerage, and are deficient in light, in ventilation, and in water supply. We are, therefore, very glad that the problem of finding how such evils can be effectually remedied, has at last been recognised as a national matter. Many attempts, excellent and successful so far as it has been possible to carry them out, to meet the evils have been made, and are being made by private individuals; and, to some extent, by corporations; and here and there such efforts may have been sufficient. But in large towns and cities, and most markedly in the province of overcrowded houses, called London, private benevolence cannot do more than nibble at the fringes of the subject. Lord Salisbury, in moving for the Royal Commision, dwelt on the greatness of the work to be done, and on the difficulties that beset the question to be enquired into; but though it would not be easy to exaggerate these, the difficulties have to be faced, and the work required has to be done for the sake of society in the future; and the very magnitude and difficulty of the work make it all the more a worthy task for a great and wealthy people to perform, and above all to perform well and wisely.

The Government accepted Lord Salisbury's motion, but with the omission of the words limiting the enquiry to "populous places," so that it will extend to the housing of the poor in country places as well as in towns. The Commission is a strong one, and the fact that the Prince of Wales is a member of it gives an additional and most welcome guarantee that the enquiry made will be a thoroughly searching one. The Commission will assuredly have no difficulty in obtaining evidence, should they need any, as to the disgraceful condition of masses of the dwelling-houses which the working classes are obliged to inhabit, but they will most desire and need information from all who have had actual experience in devising and carrying out schemes for supplying improved dwellings for the classes concerned, and who, be they individuals, companies, or corporations, have acquired a practical knowledge of the requirements that have to be met, the difficulties that must be overcome, and the dangers that ought to be avoided. The absence of certain names of well-known specialists, if we may so call them, in this subject from the Commission is doubtless due to the belief that they can render more valuable service as witnesses than as members of the Commission. The two greatest difficulties that have to be encountered are, how to provide in all instances fitting and satisfactory dwellings for the working classes before actually turning them out of those that have to be improved or destroyed; and how decent and wholesome house-room is to be provided for those workers who find two or three shillings a week for rent a very heavy burden. This rent difficulty has to be met somehow, if unhealthy and demoralising homes and dangerous overcrowding are to be done away with; and the former difficulty has to be overcome, or the destruction of rookeries and slums in one district can only lead, as it has already led, to the creation of new, and perhaps still worse, slums and rookeries in neighbouring districts.

The objects of the Metropolitan Board of Works Bill, which was read a second time in the Lower House on Wednesday, are twofold:—Firstly, to clearly define and enlarge the powers of the Board to impose rates upon the inhabitants of the metropolis for carrying out any scheme that may to the Board seem to be for the good of the ratepayers; and, secondly, to empower the Board to assist any ratepayer who has undertaken to "work out a great principle," *e. g.*, to assist him to fight a water company or a gas company, should either be imposing illegally high rates. This seems very kind and paternal on the part of the Board, but may one ask, who will protect the ratepayers against the Board of Works?

At the last meeting of the Clinical Society, on February 22nd, Mr. Mansell Moullin read a paper on "Thrombosis of the Vena Cava," and exhibited a living subject in whom he had diagnosed the presence of this condition. Mr. Clement Lucas brought forward a case of Charcot's joint disease, which gave rise to a discussion upon somewhat the same lines as the debate at the Pathological Society a short time ago, upon the same subject. Additional interest was, however, infused into it by a short speech by Dr. Moxon, whose voice has of late years been too seldom heard at the Societies. In a few sentences, enlivened by some characteristically delicate touches of sarcasm, he justified his own scepticism as to the immediate connection subsisting between arthritis and locomotor ataxy, and showed that the too close observation of cases of spinal cord disease, might lead to the accumulation of a mass of "epiphenomena," quite as characteristic of simple visceral disorders as of any deep-seated nervous lesion. Dr. Buzzard, on the other hand, maintained his view of the central origin of the disease, which he was inclined to localise in the medulla oblongata, whilst Dr. Julius Althaus spoke with equal confidence as to the influence of peripheral neuritis in its production.

Mr. Noble Smith read a paper "On Dislocation of Semi-lunar Cartilages," which was followed by a short debate, in the course of which two practical points of some importance were elicited. Treatment by complete rest was strongly condemned by more than one speaker, and the use of free movement insisted upon, after the dislocated cartilage is fully replaced and fixed by the apparatus described by Mr. Noble Smith, and devised by Sir James Paget. A useful method of reduction was also mentioned by Mr. Tyson. Several living specimens of interest were exhibited, of which we publish a list in another column.

We are requested to state that the Committee appointed by the Clinical Society to investigate myxœdema, have drawn up a schedule of enquiry. A copy will be forwarded to any gentleman who has had cases of this disease under his care, on application to Dr. Hadden, 21, Welbeck-street, London, W.

The discussion at the Medical Society on the cold-bath treatment of enteric fever, opened last week by Dr. Sidney Coupland, was continued, and after a prolonged and interesting discussion, was brought to a close on Monday evening last. Sir Joseph Fayrer, the President, contributed a curious example of the soothing and non-injurious effect of even long-continued application of cold water to the head. In certain parts of India it appears that mothers who must go out to work place their infants under running water, the body is swathed in clothes, and so placed that it cannot get wet, the stream of water is then so conducted that it trickles over the head and then runs off. Children thus treated remain asleep for many hours together. The typhoid discussion was animated, but as will be seen by our subsequent comments, it turned warmly in support of Dr. Coupland's contention. Even after being prolonged to a late hour, the list of speakers was not exhausted. Under the circumstances, we thought it a little unusual that precedence was given to a paper (which was read by the Secretary), the author of which was not present; while several gentlemen were present, who had signified their wish to speak, and had come expressly to do so.

Dr. Cayley resumed the discussion, and announced himself as a firm believer in the value of the antipyrexial treatment, quoting from a wide experience, both at the Fever and the Middlesex Hospitals. He criticised Dr. Bristowe's conclusions, and pointed out that the two cases which had so impressed him (Dr. Bristowe) with the dangers of the cold bath, could not be regarded as instances of the antipyrexial plan of treatment as advocated by Dr. Coupland in his opening paper. Indeed, he (Dr. Cayley) questioned whether it was advisable to adopt this treatment as a last resort; for its full value could only be expected in cases in which it had been commenced early, and before a patient's vitality had been lowered by the excessive tissue change incidental to long continued high temperature. As regards the value of statistics, he agreed that they should be carefully used; but with proper precautions, in experienced hands, and conforming to certain canons, they might be of the greatest service. He alluded to the effects of age, nationality, characters of different epidemics, and various other causes as influencing mortality returns, and concluded a brilliant speech with the following conclusions:—The cold-bath treatment, when judicially carried out (1) answered the physiological requirements of the case; it kept down metabolism, and thus lessened the "typhoid state." It had a stimulant effect on the vaso-motor system, and prevented granular degeneration and softening of the tissues. (2) The symptoms were materially alleviated, when the temperature was *kept down continuously*. (3) Complications were less frequent and less severe, as the tissues were better able to resist the effects of the disease. (4). Mortality was reduced.

Dr. Samuel West commenced by quoting Liebermeister's opinion that the temperature was the real index of the severity of fever; and then expressed the opinion that this was a one-sided theory, and that, therefore, we were not justified in attributing any favourable results which followed cold-bathing, to the fact that the temperature had been lowered; in other words, that we were not justified in arguing from results. As regards statistics, they were often fallacious, either because of the inaccuracy of the observations, or from insufficiency of the data, or various disturbing causes. Nevertheless, Dr. West quoted the statistics from St. Bartholomew's Hospital for the past 23 years: which were interesting, as bearing out the generally accepted view that the disease is more severe in some years than in others, irrespective of treatment. Appreciating the unreliability, therefore, of mere statistics, he secured the written opinion of the physicians; and as being the general impressions of a wide experience, he thought they would be interesting. It was remarkable, too, how nearly they coincided; thus it was necessary to read only one, and he selected the opinion of Dr. Andrew. This physician never used the bath in ordinary cases, with a temperature under 105° F. He was guided also by the character of the epidemic. He preferred milder measures, such as cradles to keep off the clothes, and a lighter supply of bed-clothing, and a lowered temperature of the room; but thought the bath necessary in hyper-pyrexia. Dr. West's own view was that the cold-water treatment was based on a one-sided view of the process of fever.

Dr. Gilbart Smith had been surprised to hear Dr. Bristowe assert that this plan of treatment had been given up in many hospitals. He showed that in some form or other it was still used largely, and with success, at the London Hospital; and he quoted the statistics of typhoid fever, treated from 1878–1883, giving a total of 456 cases, with a death-rate of 14·9 per cent. He thought it would be well if, owing to the fatigue and trouble of lifting patients into and out of the baths, similar effects could be obtained by other and less troublesome methods, as, for instance, by cooled air; for quiet, he thought, was more valuable than any good that could be got from sponging or bathing; hence, he would reserve these methods for the severer cases only.

Dr. A. T. Myers contributed the statistics and the results of treatment obtained at St. George's Hospital. He said the rejection of statistics amounted to the rejection of the whole method of inductive philosophy; and that the faults lay not in the statistics themselves, but in the logic of those who used statistics. He was particularly struck with Dr. Coupland's figures; of 52 cases admitted during the first and second week of the disease not one had died, whereas, on the "alcohol and expectancy" treatment pursued at St. George's Hospital, no such differences could be traced in the cases admitted early and those which were admitted late on in the disease. The total mortality in St. George's for the past six years amounted to 24 per cent. He believed this might be explained, in part, by the individualism of the patients, and partly by the strict use which was made of the term typhoid fever, only typical cases being included. Dr. Mahomed's paper endorsed the value of the method; he believed that a judicious use of the bath would save about six per cent. of the now fatal cases; habits had much to do with the cause of a fever, and the cold bath was useful in checking bad habits; he would not use them below 70° F., and would not extend them beyond five minutes; the impression of greater cold and longer periods was too profound; he cautioned against an injudicious use of this remedy.

Dr. Broadbent's testimony in favour of cold bathing was emphatic: he said even if he had come to the discussion with an unfavourable opinion, he should have had to change it after Dr. Coupland's and Dr. Cayley's papers; a case for cold bathing had never been better made out than by these speakers. He pronounced himself in its favour, not on these grounds only, but as the result of a long and varied experience of fever cases. Dr. Maclagan took an opposite view: cold bathing, he said, could not fail to drive the blood to the internal organs, and must necessarily increase the dangers of bowel lesions, a fact clearly brought out by the statistics before them. Dr. Sansom added his testimony in favour of the practice, which, he said, he had himself adopted, in one way or another, since 1871. Dr. Fowler had been connected with several hospitals; at one he had seen the alcohol treatment tried; at another the expectant method; and at his present hospital, the Middlesex, cold bathing was the plan adopted; he had no hesitation in expressing his adhesion to the last-named plan of treatment. Dr. Coupland, in reply, was pleased to find such a large preponderance of evidence in favour of the plan he had advocated; and as a reply to an objection which had been raised by one or two speakers, he read from a letter just received from a private practitioner, formerly one of his house-physicians, at the Middlesex Hospital, the following statements:—"I find no difficulty in carrying out the bathing of typhoid patients in their own homes," and "however much opposition there may be on the part of friends at first, they are soon convinced of the beneficial effects of the bath."

At the Royal Medical and Chirurgical Society, on Tuesday Mr. Chavasse, of Birmingham, read a paper on "Neurectomy of the Second Division of the Fifth Nerve, including Meckel's Ganglion." Surgeons are well acquainted with cases of intractable neuralgia which sometimes resist every treatment, and they will be grateful to Mr. Chavasse for introducing to their notice an operation which promises to be of some real service. The paper will be found fully reported in another part of this journal. At the same meeting, Dr. Gibbes showed a remarkable series of microscopic preparations of putrefactive bacteria. They were admirable specimens of double and triple staining, and thanks to the use of well-constructed condensers (on Dr. Gibbes' own model) the bacteria were unusually clear and distinct. Mr. Heath exhibited a man from whom he had removed the upper extremity, including the scapula and part of the clavicle. This operation only appears to have been carried out in some eleven or twelve other instances.

The annual meeting of the Royal Medical and Chirurgical Society will be held this (Saturday) evening, when the following list of officers and other members of Council will be balloted for:—President—*George Johnson, M.D., F.R.S. Vice-presidents—*William Overend Priestley, M.D.; Reginald Edward Thompson, M.D.; Richard Barwell; William Scovell Savory, F.R.S. Treasurers—Charles Bland Radcliffe, M.D.; John Cooper Forster. Secretaries—Richard Douglas Powell, M.D.; Matthew Berkeley Hill. Librarians—Wilson Fox, M.D., F.R.S; John Whitaker Hulke, F.R.S. Other members of Council—George Fielding Blandford, M.D.; Dyce Duckworth, M.D.; Samuel Jones Gee, M.D.; Frederick William Pavy, M.D., F.R.S.; *Charles Theodore Williams, M.D.; *John Croft; *Sir William MacCormac; *Thomas Pickering Pick; *William Sedgwick; William Spencer Watson. (Those gentlemen to whose names an asterisk is prefixed, were not on the Council, or did not fill the same office last year.) Sundry minor changes in the by-laws will also be proposed. The Council, we find, being anxious to increase the number of old standard works in the library, invite Fellows to inform the Resident Librarian, when opportunities occur for obtaining such books. We have noted with satisfaction the increased vitality and interest which have characterised the meetings during the past two sessions; and hope, and doubt not, that under the new President, this increased vigour will continue to manifest itself.

The sub-committee, nominated by the President, after the last meeting of the Royal Medical and Chirurgical Society, to report further on the microscopical preparations of cholera exhibited to the Society, have reported as follows:—"We have examined the microscopical preparations exhibited to the Society on February 12th, 1884, and have found in them the micro-organisms described by Dr. Straus; but do not observe any features of the bacilli in the tissues that can be considered as specific. (Signed) E. Klein, M.D., F.R.S.; Heneage Gibbes, M.D.; Victor Horsley, B.S., F.R.C.S."

Dr. Angel Money writes, with reference to our last week's note on his paper on "Infantile Paralysis," read at the meeting of the Pathological Society, "you say Dr. Money contending that the chief cause was a

faulty blood supply and not an inflammation of the grey matter. This statement does not exactly represent what I maintained at the meeting of the Pathological Society. I believe that inflammation of the grey matter undoubtedly exists in cases of infantile palsy, and that this inflammation is the result of vascular disorder."

The new Military Medical Society of Woolwich have recently been discussing how antiseptic surgery may be carried out on the field of battle and in war—a subject of vital importance at any time, but especially so in these days of gigantic and universal armaments. It is quite impossible to say how many lives might not have been saved in the late wars, could such a system have been at all adequately carried out. A paper by Surgeon-Major Godwin introduced the subject. He entered into the now well-worn theory of inflammation and suppuration, and pointed out how they were no necessary result of a wound, and that repair could be obtained without them, and with greatly diminished risk to life and limb. He then pleaded for the introduction of *Listerism* as routine treatment in all military hospitals and schools, in order that army surgeons, and indeed the whole department, might have a thorough grasp of the subject and be familiar with its every detail; this, he said, would be the first step towards its introduction into actual warfare. Reference was made by several speakers to the necessity of every surgeon being familiar with the treatment, and provided with the means of carrying it out. It was of no use, they urged, if not done thoroughly and continuously, and to be really effective it should be commenced before decomposition had taken place; for this process once set up was difficult to arrest, wound fever set in, and death was only too often the result. The chief difficulty lay in providing adequate measures at the front. This, it seems to us, is only to be done by the surgeons in charge of the first or field-stations being thoroughly imbued with a sense of the importance of asepsis, and provided with the means of properly carrying out its principles. No amount of subsequent care and skill at the transfer and dressing stations will avail, unless this first condition can be accomplished.

It is needless to say that Sir Joseph Lister, in the course of the debate, spoke with his accustomed enthusiasm in favour of the project He referred especially to the value of corrosive sublimate solutions as being in some respects superior to carbolic acid, in that they were non-volatile, and therefore useful for cleaning sponges, hands, instruments, &c. He spoke also of iodoform and its advantages, and mode of use. There were many other speakers, including the Director-General, who in an excellent speech, while expressing his full approval of the idea, drew attention to the material difficulties of the question; he showed the insufficiency of all the hitherto suggested methods for providing each man with a complete occlusive and antiseptic dressing for first use. Apart from other difficulties, he said, he could not rely on the soldiers themselves. On the other hand, he was in favour of all army surgeons being well drilled in the use of the antiseptic methods, and well provided with the means of carrying them out on the field.

We are a little inclined to join issue with Sir James Hanbury, who seemed to think that our greatest difficulties will be experienced in colonial and distant, rather than in European wars, for in the latter we have "all the resources of civilisation to fall back upon." The facilities of transport, by passing the wounded rapidly through a large number of hands, in our opinion, will immensely complicate the question; besides which, if past experience be worth anything, the strain on the department will be proportionately greater owing to the larger numbers engaged and wounded. In our colonies and outlying countries, the numbers engaged are much smaller, and the wounded have a better chance of early and efficient attention. In a recent work, Dr. Brown gave his Zulu experiences, and recorded instances of bullet wounds healing by the first intention; a result, we venture to think, which was never attained during the Franco-German war. On the other hand, the immense amount of human life concerned after a large battle in a European country—as, for instance, on the 14th, 16th, and 18th August, 1870—renders the need for antiseptic surgery the more pressing, and its attainment the more difficult. *Apropos* of the suppression of the carbolic spray, we are inclined to think that, whereas in small wars, and with few wounded to attend to, it may be safe to operate without it; in large wars, with necessarily overcrowded, ill-adapted, and badly ventilated wards, its use will prove of the highest value, not to say of absolute necessity.

In a recent number of the *Centralblatt für Chirurgie*, Dr. Lesser made a suggestion as to how a first antiseptic dressing might be constructed so as to be conveniently carried by the soldier. He would give each man one less than the normal twenty cartridges, and would replace this by a cartridge-case filled with an antiseptic powder, a mixture of iodoform and boracic acid. In addition, the man is to have a bandage soaked in spermaceti, a little absorbent wool, and a three-cornered handkerchief. The mode of use is simple—the wound is sprinkled with the powder, one or two turns of the bandage are then made over this, then the wool is put on and over this again the remainder of the bandage, and, finally, the three-cornered handkerchief. "In this way, the cartridge, which carries death for the enemy, carries for us the means of healing wounds antiseptically, and so saves the lives and health of our wounded soldiers." We sincerely hope that some practical outcome will be the result of this discussion.

The success which has attended the formation of the Medical Sickness Annuity and Life Assurance Society at so early a period of its development, when the profession as a whole have hardly acquired a knowledge of its existence, is in the highest degree satisfactory. Over 40 gentlemen in various parts of the kingdom have consented to act on the General Committee, and from their number a Provisional Executive Committee, which has already held several meetings, has been formed. The advantages offered to those who assure in this Society are as follows:—1. A certain sum per week (from two to four guineas),

according to amount of premium, during illness. 2. An annuity after 65 years of age. 3. A certain sum at death. The Society is based on principles of purely mutual assurance, the whole of the funds becoming the property of the members, whose liability is strictly confined to the quarterly premiums. The Society will be registered under the Friendly Societies Act.

It cannot be too widely known that, though this Society took form at a meeting held during the session of the British Medical Association at Liverpool, it has no direct connection with that body, but is open to all registered medical practitioners in the United Kingdom. The number of gentlemen who have joined is already sufficient to augur well for its future success. The opinion of Mr. Neison, F.I.A., as a leading actuary, has been obtained on the rules and tables, and, after examination, he has certified that in his opinion they form a sound basis for the work of the Society. Copies may be had of the Secretary, Mr. C. J. Radley, at the temporary offices of the Society, 26, Wynne-road, Brixton, S.W.

There was a general rise of the death-rate throughout the country last week. The increase in London was not so marked as elsewhere, for while in the metropolis the deaths only mounted from 1,528 to 1,552, and the death-rate from 19·8 to 20·2, in the 27 other great towns (whose aggregate population is three-quarters of a million more than that of London), the number of deaths rose from 1,839 to 1,986, and the death-rate from 20·1 to 21·1 per 1,000. In the eight large towns of Scotland the increase was still more marked, the death-rate having shot up from 20·9 to 22·6. This rise in the death-rate is not connected with any marked increase in the fatality of zymotic diseases; for in London the zymotic death-rate stands at exactly the same point as last week, viz., 2·7; in the 28 large towns it has only gone up a decimal point, from 2·6 to 2·7; and even in the Scottish towns, where the general death-rate has risen by 1·7, the zymotic rate has only risen 0·2.

The London returns contain nothing especially noteworthy, except that small-pox appears to be somewhat on the increase, the metropolitan asylum hospitals being fuller than they have been since August year. A death in Guy's Hospital was recorded from "malignant pustule." The following table shows, at a glance, the comparative prevalence of the different zymotic diseases in London during the first eight weeks of the present year.

Diseases.	1st Week.	2nd Week.	3rd Week.	4th Week.	5th Week.	6th Week.	7th Week.	8th Week.	Total.
Small-pox	6	2	5	2	1	4	2	4	26
Measles	48	47	42	42	30	19	35	42	305
Scarlet Fever	33	38	34	32	33	34	22	37	283
Diphtheria	16	15	16	16	23	19	26	14	145
Whooping-cough	68	63	69	80	85	78	83	82	608
Enteric Fever	12	17	24	20	14	21	21	12	141
"Fever"	2	3	2	2	2	1	1	0	13
Diarrhœa and Dysentery	8	4	10	9	7	10	17	17	82
Simple Cholera	–	–	–	–	1	–	1	–	2
Total zymotic deaths	193	189	202	203	196	186	208	208	1,585
Zymotic death-rate	2·5	2·5	2·6	2·6	2·5	2·4	2·7	2·7	—

The Registrar-General for Ireland has just issued his return for the last quarter of last year. The birth-rate was 21·2, or 1·1 below the five years' average, and the death-rate 16·2, or 1·2 below the average. The number of deaths registered during the quarter were 2,236 fewer than the number registered in the corresponding quarter of 1882, though the deaths from zymotic disease were higher by 87 than in that quarter. Even with this increase, however, the zymotic death-rate of Ireland for the quarter in question, viz., 1·6, compares most favourably with that of England, which during the same quarter was 2·27. The following represents the respective mortalities from the chief zymotic diseases in the two countries during the quarter:—Small-pox, England 731, Ireland 2; measles, England 2,493, Ireland 142; scarlet fever, England 4,197, Ireland 599; whooping-cough, England 1,794, Ireland 418; diphtheria, England 1,227 Ireland 59; diarrhœa, England 3,148, Ireland 317. In the English returns the fevers are all placed under one head, the deaths from all the different forms during the quarter numbering 2,197; in Ireland the deaths number 413, distributed as follows: typhus 182, enteric 175, simple continued and ill-defined fever 56. When we remember that the population of England is about five times as numerous as that of Ireland, it will be seen that, in spite of his unsanitariness, Paddy beats us hollow in his resistance to all the zymotic diseases, except whooping-cough and fever. In England 11·8 per cent. of the total deaths during the quarter were due to zymotic disease; in Ireland only 9·6 per cent., and this figure is much higher than the average.

A death under anæsthetics occurred at the New Hospital for Women, on the 22nd ultimo. The patient was a woman, aged 32, who suffered from extensive disease of the kidneys—as was verified *post mortem*—and went into hospital by the advice of her family doctor. It was found necessary to perform an operation, and the A,C,E, mixture was administered by Mrs. Marshall, one of the medical officers of the hospital. The patient was six or seven minutes getting under, and the operation had scarcely begun when respiration stopped. It was kept up artificially for an hour and a half, but without avail. Mrs. Garrett Anderson, who gave evidence at the inquest, considered that death was due to syncope.

The *Morning Post*, which is always well informed on medical topics, has published a very sensible article on anæsthetics. Commenting on the satisfactory statement that only nine deaths are reported in the medical journals to have occurred in the United Kingdom from the use of anæsthetics in 1883, whereas 28 were reported in 1882, and fifteen in 1881, it calls attention to the fact that in many of these cases the fatal result may have been due, not to the anæsthetic, but to the operation. It is exceedingly difficult, it continues, to differentiate the two causes, and in the old days when chloroform was unknown there were numerous deaths from sudden stoppage of the heart's action, caused by mere fright before any application of the surgeon's knife.

SPEAKING of nitrous oxide, the *Morning Post* fears that the growing practice, especially among dentists, of administering it single-handed, will be productive of mischief, and will tend to discredit its employment, even in a proper fashion, and it doubts "whether the theory and practice of this and other anæsthetics is sufficiently taught in some of our medical schools. A special certificate from an expert is required to qualify a medical practitioner for performing the very simple operation of vaccination; and it might be well to apply at least an equal test to the student's knowledge of the art of sending his patient to the realms of happy unconsciousness, and, what is more, of bringing the patient back again."

NOT long since, we called attention to the discreditable condition, from a sanitary point of view, of a large proportion of the better class of houses in London. Our contention is borne out by the report of the Council of the London Sanitary Protection Association, presented at the general meeting, held on the 23rd ultimo. Of 404 houses inspected by the engineers of the Association, during 1883, most of them being private dwellings in London and the neighbourhood, two per cent. were found to have their drains utterly closed, and entirely unconnected with the sewer, so that all the foul matter sent down the sinks and soil-pipes simply soaked into the ground at the basement of the houses. In twenty per cent., the soil-pipes were leaking, allowing sewer gas, and in many cases liquid sewage, to escape into the houses; in 23 per cent., the overflow-pipes from the cisterns led directly into the drains, allowing the sewer gas to contaminate the water in the cisterns, and in many cases to pass freely into the houses; while in 67 per cent., the waste-pipes from the baths and sinks were not properly disconnected from the sewers. These figures are very startling, as showing in how large a proportion of otherwise well-formed houses the very A. B. C. of sanitary science is disregarded. There is no doubt that both the London Sanitary Protection Association and the Sanitary Assurance Association—both of which have held their third annual meetings since our last number appeared—are doing most valuable work towards the improvement of the health of the better classes.

IN one of the most striking scenes of a novel published not long ago, the hero is represented as surreptitiously peering through the windows of a gymnasium and watching the heroine performing on the trapeze. The exercise is not recorded to have had any injurious effect on the performer, but Mr. Percy Dunn has written to a morning paper, strongly condemning the use of such violent athletics by ladies. It is essential to recollect, he writes, that inasmuch as the muscular development of woman is naturally less than that of man, there are many reasons for believing that any attempt to engage in severe muscular exercise is bound to produce in woman some distortion of the frame. For instance, the large mass of muscles composing the abdominal wall developes much more readily than do the muscles of the back. This, together with the fact that the generality of movements in gymnastics implies a bending forward of the upper part of the body, causes the girl to stoop, and the back in time exhibits an ungraceful rotundity.

MR. DUNN further complains: — Many girls are allowed to "take up" gymnastics who are physically unfit for any such exercise, and to require one such girl to perform a severe gymnastic feat savours of an unpardonable indiscretion, when on the completion of her task she retires to a seat, breathless and deadly pale, indicating the extent to which her heart has suffered from the exertion. He, therefore, thinks that no parellel bars exercise, no trapeze, no horizontal bar or ladder exercise should be permitted; but dumb-bell practice *ad libitum*, combined with as much drilling as may be desirable; and lastly, no girl should be allowed to enter a gymnastic class unless she can produce a medical certificate that she does not suffer from any organic insufficiency which might be aggravated by the physical efforts indulged in.

WE hesitate to criticise Mr. Dunn's anatomical circulation; but arguing from that light of nature which is so kind to the student, the practitioner, and even to the writer, we should have been inclined to contend that hypertrophy of the abdominal muscles was impossible without an equal hypertrophy on the part of their antagonists, especially as in any position approaching the erect, the latter have to work against the force of gravity, which is usually an ally of the abdominal muscles. Besides, we fancy it would have fared very much better with many married ladies, both in pregnancy and confinement, if they had cultivated their abdominal muscles in their youth. Is not a round back due much more to unantagonised pectorals than to unantagonised abdominals?

A FANCY-DRESS ball was given at Willis' Rooms on Tuesday week, in aid of the fund for establishing the New National Italian Hospital, which has recently been opened at 41, Queen Street, Bloomsbury, the guests including most of the more prominent and influential members of the Italian colony in the metropolis. The hospital, which is likely to benefit substantially by the entertainment, owes its existence mainly to the philanthropic efforts of Cavalier Ortelli, who has contributed 150,000 lire, while it has been zealously supported by the Italian Ambassador, Count Nigra. Signor Sperati has also contributed large sums of money to the project. As in the case of the German Hospital at Dalston, it is not proposed to draw a hard-and-fast line in the matter of the nationality of the patient, although of course it will be devoted mainly to succouring the compatriots of those to whose efforts its addition to the long list of benevolent institutions in London has been almost exclusively owing. At present it only makes up eighteen beds, but it has room for thirty; and it is intended to add a dispensary for out-patients. Its staff consists of four medical officers, attending in turns, and the nursing is in the charge of skilful Sisters of Charity from the principal Italian hospitals.

The purity of our food supply never fails to form an interesting topic. Most articles of food are capable of adulteration, and it often becomes a question whether we are prepared to put up with this, rather than as to the precise amount of damage likely to result from the added materials. Copper has been regarded as an advantage as a nervine tonic, dilution of milk is constantly advised in the artificial feeding of infants, but we all wish to know, as far as possible, the precise nature and proportions of the added ingredients, and for greater security on these points, we prefer making the addition ourselves. Purity does not, however, depend solely on absence of intentional adulterations. In fact, it is certain that the sins of omission, of ignorance, and neglect on the part of our food purveyors have far more dangerous consequences to health than their wilful sophistication of the wares they sell. A hundred deaths have been probably caused by carelessness as to dairy drainage and water supply, for one that is traceable to adulteration in the popular sense of the term.

At the last meeting of the Lambeth Vestry, the medical officer reported the results of an inspection of the bake-houses in the parish, in one hundred and thirty-four of which improvements were found necessary. Many were declared to be in a highly unsanitary state, and in some sewage was found percolating through the floor. The high temperature to which bread is exposed in the baking no doubt takes the sting out of any germs that the dough may have contracted relations with. Still, it is not pleasant to think of our staff of life being possibly made in a deadly atmosphere; and where there is such carelessness as to the simplest sanitary rules, it is difficult to get over the idea that there may be equal want of care as to cleanliness in other respects. Those who have read the report on the state of London bake-houses, presented to the Government by Mr. Tremenheere some twenty years ago, will well remember the horrible descriptions he gave of his experience in those loathsome cellars—the festoons of cobwebs hanging from the rafters, the animals crawling about the kneading-trough, the smells from the drains, and the perspiration dropping from the faces of the bakers into the dough as they kneaded it. In the district of an energetic health officer, such scandals are happily impossible now, but the experience of the Lambeth inspectors shows that it requires strict and constant supervision to keep the bakers up to the sanitary mark.

It is no excuse that other countries are even behind us in the matter of sanitation; still there are some, whom it may console to read what an American contemporary found in certain transatlantic bake-houses. "In one place we found the cat and dog asleep in the kneading-trough, fowls running around and perching on the various utensils, and a general air of filth and lack of thrift. In one shop the kneading-trough was connected with the sewer, by means of an untrapped waste-pipe; in another the soil-pipe had burst, and the floor was flooded with liquid filth. The baker said that 'that always happened after a rain-storm.' I have seen a baker mixing his bread with hand and arm covered with the eruption of eczema. He said that 'the doctor told him the dough was good for the disease.'"

Talking of food, it is curious what mistaken notions prevail about the preparation of various articles. A short time since a speaker in the cause of temperance urged the disuse of alcohol, as it was not a natural product, but resulted from fermentative decomposition. Hard words and true, and likely to catch the popular fancy and largely spread. But what a discovery to make! Why not have gone a step farther, to describe other forms of fermentation, the obvious result of which would have been the wholesale elimination of some of our commonest articles of diet? Without entering into the question of how far all plant life gains tissue from the fixation of carbon from carbonic acid—the ghost of decayed tissues—it might be worth remarking that the objection urged would apply also to bread. Our indebtedness to materials which are not "natural products" will not cease until we agree to discard all the works of man, even railways, houses, and clothes; and we venture to hope that the day is yet distant when the most rabid abstainer would urge such a course. Even in a good cause truth should be regarded, and truthful inferences encouraged.

There are, and have been for some time, says the *Army and Navy Gazette*, two vacancies on the list of Inspectors-General of Hospitals and Fleets. At the end of this month, Deputy-Inspector-General James N. Dick, now in charge of Malta Hospital, will have completed the necessary period of service for promotion, and will be gazetted to one of the vacancies. Another officer is also qualified, but, for some unaccountable reason, has not yet been promoted.

A correspondent writing to us from Glasgow, with regard to our article on "The Lash" in a recent issue, says:—"I lived in Toronto, Canada, for some years, and tried my best, through the press there, to fight against the use of the lash. One case there, about two years ago, roused great indignation. An exceedingly graphic, and therefore horrible, report of its infliction was ably written by a reporter to one of the local papers, so that the public for once realised what the penalty really meant. In that case also the penalty had been ordered in two instalments. Several writers, including myself, made the press ring with the subject, and finally the second instalment was remitted. I do not think there have been any 'repeated floggings' adjudged since."

The French ministry has requested an opinion from the Paris Academy of Medicine, as to the propriety of allowing the importation of American pork, considering the danger of introducing trichinosis into France. If the same request had been addressed to the Academy before an arbitrary ministerial decree prohibited its import, the answer received might have done something towards preventing that mistaken course of policy, which has inflicted much hardship on the

working classes in France. The Academy appointed a committee consisting of Professors Bouley, Brouardel, Chatin, Colin, Laboulbène, with Dr. Proust as reporter. Dr. Proust's report has been very favourably received and generally agreed to, for Professor Paul Bert's eccentric statement that trichinosis prevails extensively in France, but has been mistaken for typhoid fever, has produced little or no effect. The Academy finally resolved—1. An epidemic of trichinosis cannot be confounded with one of typhoid fever, for though in one of its phases it may present symptoms of a typhoid character, there is no identity between the two diseases, and the evolution of trichinosis will always allow of its diagnosis being established. The symptoms, progress, duration, pathological anatomy, and nature of the two diseases, are absolutely different, both in isolated cases and in the epidemic form. 2. No case of trichinosis has as yet been observed in France or England, as a consequence of the consumption of salted provisions brought from America, and the importation of such food should be permitted. 3. It would be advantageous to create a common understanding with the countries importing trichinosed meats in relation to the special measures to be enforced as a guarantee at the export ports. 4. Instructions should be prepared and widely distributed, insisting upon the effectual cooking of such meats, and all tradesmen selling them should affix to them these instructions.

At a meeting of the Conseil d' Hygiène Publique, M. Leblanc reported that rabies and hydrophobia in Paris continue to sensibly diminish in the Department of the Seine. In 1881, the number of cases of rabies verified was 615 ; in 1882, 276 ; and in 1883, 182. In 1881, there were 729 animals bitten; in 1882, 294; and in 1883, 198. The same rate of decrease has been observed in the number of persons bitten, viz., 156 in 1881, 67 in 1882, and 45 in 1883. The best result of all, however, is the decrease of cases of hydrophobia, which have declined from seventeen in 1881 to eleven in 1882, and to six in 1883.

On Monday last M. Pasteur communicated to the Paris Academy of Science some very interesting results of his recent experiments with the poison of rabies. He finds that if the virus is brought into direct contact with the brain, an acute attack invariably follows, but that if it is injected into the veins, the result is more often a chronic form of the disease, unaccompanied by barking or ferocity. Fowls and pigeons inoculated with the poison show signs of the disease, but recover from it. The infection can be communicated by inoculation with portions of the spinal cord or nerves of an animal suffering from rabies. But the most interesting statement made by M. Pasteur is that he can render dogs insusceptible of the infection, by inoculating them with a modified virus.

Prof. Kowalewski, of Odessa, has received a call to the Zoological Chair at the new University of Marseilles, the salary being 15,000 francs per annum.

An Anthropological Society has been founded at Bordeaux, with Dr. Azam as president, and Dr. Testut as vice-president, both being members of the Faculty of Medicine of Bordeaux.

The death of an Italian practitioner, who once played a conspicuous part in the revolutionary movement, is recorded. Dr. Caspar Belcredi, who died near Bergamo on the 16th ultimo, in the 84th year of his age, was the oldest survivor of the "Young Italy" party, and was once Mazzini's private secretary. He was born at Pavia, and came of a noble stock ; he devoted himself to the study of medicine, joined the revolutionary party in 1833, was compelled soon after to flee to Switzerland, and subsequently practised for some years in France. He returned to his native country under the amnesty of 1839, but having become again implicated in the revolutionary propaganda, had again to take flight in 1847, England being now his refuge. It was at this time that he became secretary to Mazzini. In 1859, he was again allowed to return to Italy, where he settled down at Bergamo, gave up politics, and achieved a considerable reputation as a physician.

According to the *Pharmaceutische Zeitung*, the proposed medical reform in Prussia will include the appointment of Local Sanitary Councillors, and the establishment of Councils of Provincial Physicians, which would be expected to assemble at least once a-year. No provision is to be made for the representation of the apothecaries.

Some weeks ago we announced the fact, that the Berlin Medical Faculty, at the request of the Minister of Public Instruction, had taken the question of vivisection into its earnest consideration, and it had come to an unanimous conclusion as to the opinion upon the subject, which it wished to be submitted to the Legislature during the approaching discussion. The Committee holds that vivisection is absolutely necessary, whether for the purposes of scientific enquiry or medical education ; and that without its aid, progress in physiological investigation is not possible, nor can the student attain a proper idea of some of the most important vital processes. A series of experiments upon animals are indicated, which are essential for medical instruction, if the laws of the influence of the nervous system on digestion, circulation, &c., are to be thoroughly understood and rendered capable of practical application for the restoration of health ; the present time, moreover, is one in which medical science may be expected to derive especial advantage from these experiments in the investigation of epidemic and contagious diseases, and the determination of the efficacy of the various measures employed for their prevention. The regulations regarding water supply, the removal and disinfection of excreta, &c., could never have been determined upon without the aid of experiments. Numerous striking examples are furnished of the enormous importance and great utility of such experiments in relation to the State and society, and to the progress of science. The report is from the pen of Geheim-Rath Professor Dubois-Reymond, whose colleagues on the Committee were Professors Virchow, Westphal, and Leibrich.

Jubilees are of never-ceasing occurrence in Germany and Austria, and with so large a number of professors to fall back upon, the source of supply for a succession of such festivities is not likely to fall short. Institutions are also to have their turn. The Würzburg University lately celebrated its 300th anniversary, and it has just been resolved at a meeting of the staff, that the centenary of the Wiener Allgemeine Krankenhaus, which was founded by Joseph II. in 1784, shall be celebrated with considerable ceremony during the summer of the present year. Its vast clinical capabilities, and the great advance it has contributed to the progress of pathological anatomy, and indeed to that of every branch of medical science, are known and appreciated throughout the medical world. The real centenary of the hospital would occur in August, but a Committee, consisting of Professors von Braun. von Dittel, Kundrat, and von Schrötter, have decided that the celebration shall take place in June instead. During August academic enthusiasm is generally on the wane in Vienna, or is transferred to some distant city, where the attractions of a Congress are happily commingled with labours of a lighter sort.

A curious book has just been published in Sweden. It is written by a mad-doctor, and has been set up, printed and bound by his patients. This is how it happened. Amongst the inmates of the Konradsberg Lunatic Asylum at Stockholm, there happened to be a compositor, and a supply of type and a small hand-press were provided to give him occupation and amusement. One by one several other inmates became interested in the matter, and were instructed by their fellow-patient in the art of type-setting. Dr. Björnstrom, the medical chief of the asylum, gave his support to their efforts, holding that such an occupation not only provides for the insane a pleasant and useful amusement, but also, like all regular mechanical labour, tends towards their cure. He, therefore, introduced a complete printing press into the asylum, entrusted it to a patient who happened to have been a printer, and directed that all his patients who showed any inclination for the work should be instructed in its use. The thing now was to find "copy," and here again Dr Björnstrom was not at fault. He had written a work on "Diseases of the Mind and Abnormal Psychical Conditions, regarded from the Forensic standpoint." He at once entrusted the manuscript to his patients, with the result that they have turned out a book of 202 pages, the type, binding and general appearance of which are such, that no one would ever suspect that they were entirely the work of the class of unfortunates, to whose sufferings its pages are devoted.

The journalistic enterprise of the profession throughout the world is so vigorous that, if we were to herald the birth of every new medical journal that comes into our hands, we should be heralding one or more every week. The last new "bantling," for so it modestly describes itself, which appeals for notice, is one which the medical press in England may cordially welcome, and wish prosperity to. It is called the *South African Medical Journal*, and is a sheet of sixteen pages, published at East London, a town on the Buffalo river, which has risen in the short space of half-a-dozen years from being a little German village to be the third port in the Cape Colony, and an important centre of commercial activity. This is not the first medical journal that has been published in South Africa. Several decades ago, a paper was started in Cape Town, edited by Dr. Ebden, but it only lived for a year, and fell through when its editor entered the Indian medical service. After many years service in India, Dr. Ebden returned to Cape Colony, and in July last took a principle share in the formation of the South African Medical Association, with which the new journal promises to cordially co-operate.

The editor of the *South African Medical Journal* introduces his enterprise to his readers in a very modest preface, in which he apologises for his first issue ; but he has managed to put together a paper of much more interesting and varied character, than many of his bulkier contemporaries in the mother-country and other colonies. He has collected several interesting papers, but if the following extract, from one of his leading articles, is not grossly libellous, he will find the ethical function of his journal quite as important as the scientific. "None can deny," he writes, "that our ethical tone, bad as it is in England, is worse here. We know of town after town in the colony, where for a patient to suggest a consultation is to mortally offend, where the courteous assistance of one practitioner to another is a thing unknown, and where patients, in the temporary absence of their own attendant, are left to the tender mercies of chance."

Here, in London, we are rather given to be wantonly amused at the tried country practitioner, whose plaintive protest against his rival, Dr. A. B.'s treatment of him in reference to the case of Mrs. C. D., appears so frequently in small print in the *Lancet;* but we imagine that the *South African Medical Journal* might do a good work, if it could provide a similar column, in which such reprobates as Dr. A. B. might read the bare anonymous recital of their peccadilloes. Possibly they might then have the good taste to feel conscience-smitten, and take pains to avoid such alphabetical strictures in the future ; while others, trembling on the verge of ethical trespass might be kept in the right road by the fear of the matter-of-fact compositors in East London. In that town, we are glad to read, "cordial friendliness exists on all sides, and fraternal assistance is given and received," so that the editor need have no fear of reprisals.

The appointment of Sir W. Guyer Hunter, as Knight Commander of the most distinguished Order of St. Michael and St. George, was notified in the *London Gazette* of Friday week.

Dr. Bristowe's report on the Sanitary Acts, in their relation to the very poor, appearing, as it does, just after the appointment of a Royal Commission to investigate the whole subject of the dwellings of the poor, deserves and will, we hope, receive the careful attention and consideration of those whose duty it is to endeavour to probe this great matter thoroughly. As the out-

spoken opinion of one who has had many years' practical experience, we consider it especially welcome just now; for surely none are so well qualified to speak on this question as those whose business it has been to enquire into the sanitary condition of such dwellings. The problem is beset with far greater difficulties than many even of those who consider themselves quite competent to pass an opinion would admit, and is not by any means to be solved offhand on general principles or theoretical grounds. The habits of the class for whom it is proposed to legislate, cannot be revolutionised by Act of Parliament, and, as Dr. Bristowe very justly observes, slovenliness, improvidence, recklessness, dishonesty, offences against the seventh commandment, lie beyond the immediate scope of the sanitary authorities. Amongst the many difficulties in carrying out the Sanitary Acts to which Dr. Bristowe alludes are some which would not suggest themselves to those benevolent philanthropists who have made up their minds after a few days' cursory inspection. Of these we shall only mention the difficulty that frequently arises in determining what constitutes a nuisance or injury to health; dirt and entire absence of any pretence at tidiness would make a great impression on one unaccustomed to such a state, but do not in themselves imply a condition injurious to health, nor is such a tenement of necessity unfit for human habitation. If habits of personal cleanliness could somehow be impressed upon the lowest classes, so as to become a second nature with them (the very opposite being at present the fact), then we believe that the greatest obstacle would have been overcome, and improvements in their dwellings would follow without the aid of State or parish intervention.

The March number of *Blackwood* contains a passionate attack on the Medical Act of last, and presumably of this, year. It is evidently of home growth, being written in the interest of the Scottish Colleges, and in a thoroughly partisan spirit. No attempt is made at a judicial consideration of the question, and the arguments on the other side are quietly ignored. We are not concerned to defend Mr. Mundella's Act, but it is, on the face of it, an absurd contention that a measure, mainly founded on the recommendations of a Royal Commission, passed by the House of Lords after very thorough consideration, and accepted as a fair settlement of the question by the body of medical opinion outside the corporation cliques, should be such a villanous one as the writer in *Blackwood* tries to make out. Many of his objections to it are utterly trivial, and others are altogether beside the mark. It is a pity that the Edinburgh Colleges and their supporters, self-constituted or otherwise, cannot understand that they will find no sympathy south of the border. They have for years rendered more or less futile the attempts to improve medical education in England, by keeping the standard of their examinations considerably below the minimum of the English standard, and in consequence have attracted and passed men who have utterly failed to get an English qualification. For our own part, we see no reason why the Legislature should be expected to deal tenderly with the Scottish Corporations. Certainly the medical jingo who writes in *Blackwood* has not provided us with any.

THE COLD-BATH TREATMENT OF ENTERIC FEVER.

The Medical Society of London has just concluded a most instructive discussion on the above subject. When we remember how wide-spread is the disease, how insidious its onset, how rich and poor alike suffer, what a severe type it not infrequently assumes, and what a high death-rate it occasions, it will be conceded that few more important subjects could have occupied the time and attention of the Fellows. We have given the pith of the discussion in another part of this journal, and it now only remains for us to gather up the threads, and place before our readers the lessons which may not unfairly be deduced.

Dr. Sidney Coupland, to whom the Society was indebted for the initiation of the discussion, contended that the cold-bath treatment, *when commenced early, and carried out systematically*, tended to abort the disease, to minimise the sequelæ, to hasten recovery, and to lower the mortality of typhoid fever. His arguments were chiefly based on 89 personally observed and carefully recorded cases; but they were fortified and contrasted with the published results of other physicians. Dr. Bristowe led on the other side, and stated that after a fair trial he had gradually abandoned the treatment, as not answering the indications which Dr. Coupland had laid down, and, moreover, as being dangerous to life. He said he had been chiefly influenced by two fatal cases of lung collapse, which he attributed directly to the bath. His opinions were not backed, as were Dr. Coupland's, by any statistics; for he preferred general impressions in such matters to statistics, which could be made to show almost anything that was wanted.

It must be conceded with Dr. Myers, however, that the rejection of statistics is tantamount to the rejection of the whole method of inductive philosophy; and that any erroneous views, which may be inferred from statistics, depend less on the figures themselves, than on the bad logic of those who make use of them. This latter statement was abundantly manifest in the varying conclusions which were drawn from Dr. Coupland's tables by subsequent speakers in the debate. Fortunately for the subject, neither Dr. Coupland, nor those who sided with him, relied on the compiled statistics. For both Dr. Broadbent and Dr. Cayley, as physicians to the London Fever Hospital, could speak from a long and varied experience, and could give good reasons for their advocacy of this plan of treatment. It is only just to Dr. Bristowe, who was the only important opponent of the plan, to say that he was quite ready to reconsider his position, and even to go over to the enemy, if they could show that their plan of treatment offered any decided advantages; this we fully expect him to do, after the immense testimony in its favour which was adduced at the Medical Society. If Dr. Bristowe was not quite converted by Dr. Coupland's paper, the remarks of Dr. Broadbent and of Dr. Cayley can hardly fail to make an impression upon him.

We must frankly admit that we were not quite prepared for such an almost complete agreement in professional feeling on this subject. The cold-bath treatment of fever seems, at first sight, somewhat unnatural; it runs counter to some of our most cherished notions;

it goes contrary to popular traditions and popular prejudices. When a person is feverish, says the multitude, keep him warm, keep away cold draughts, lest the fever should be driven to the internal parts, lest exposure of the fevered body should favour "catching cold." It has required much effort and perseverance to show the fallacy of these views, and the natural reluctance to give up one's cherished opinions has cost many a life that might otherwise have been saved. Dr. Coupland acted wisely in collecting statistics as to the causes of death in the fatal cases, and more especially in detailing the exact *post-mortem* appearances in his own seven fatal cases. One remarkable outcome, and its correctness was amply corroborated by other speakers, was to show that pulmonary troubles are considerably lessened by this plan of treatment, these popular traditions notwithstanding. Another outcome was to show that the characteristic—the intestinal—lesions are the most serious, the most to be dreaded, and the least amenable to any form of treatment. Death, however, not infrequently occurs in consequence of other causes, and all the evidence went to show that these accidental consequences are largely and favourably influenced by the cold-bath treatment, while deaths from purely hyper-pyrexial causes are almost abolished. Dr. Cayley objected to the plan being condemned on theoretical grounds, or by those who had only tried it in a half-hearted way, and in this we cordially agree. To say that the blood is all driven from the surface to the internal organs by a cold bath is pure assumption, it is not founded on scientific reasoning, it is not corroborated by *post-mortem* examination, and as an argument therefore, it is useless either for or against.

The great question of being able efficiently to carry out the plan in private practice was alluded to by more than one speaker; and to those arguments Dr. Coupland replied by reading extracts from a letter which he had just received from a private practitioner, to the effect that he had found no insurmountable difficulties in carrying it out, and that the friends soon became convinced of the value of the plan, by the increased comfort and well-being of the patient. As to the trouble it entails, we venture to think that in so vital a matter as this, trouble will not be considered by the practitioner who has any regard for his patient; on the contrary, we think he will be glad to know, on such good authority, of a powerful and additional means for treating cases which are always full of anxiety, and often, notwithstanding great care, fatal.

PUBLIC OPINION AND EXPERIMENTAL PHYSIOLOGY.

II.

Second-hand opinions have their value and their drawbacks. In the present time of widespread knowledge and rapid progress, it is impossible for anyone to make himself fully acquainted with all the details, all the relations of the successive steps, by which results are being achieved, facts marshalled, and conclusions arrived at by the workers in the various departments of modern science. A lifetime is too brief to allow of complete mastery being gained in any one of them, and hence it follows that he who would keep pace with the times in anything outside of his own particular path in life must be content to accept and rely upon the *ex cathedrâ dicta* of recognised authorities, in the same spirit as he accepts the opinion of his lawyer—because he is specially qualified to form one on the case; and as he relies upon the integrity of his bankers—because they have established, and continue to deserve, their reputation amongst those capable of estimating it. No one can reasonably object to opinions being thus adopted; the only proviso being, that he who acts upon the conclusions formulated by others shall take all necessary care to accept only the specially expressed opinions of those whose recognised knowledge, judgment, and experience of the subject entitle them to speak with authority. The case is otherwise when a man accepts the opinions of others because they coincide with his own mental leanings or desires; because they are dazzling or seductive, or flattering to his self-love; or, again, because they are reiterated with persistent vehemence—much like the prospectuses of bogus companies, sown broad-cast, with taking titles and promises of enormous dividends. It is worse when, fascinated by such appeals to his passion or his prejudice, he refuses to hear those who speak on the other side—more calmly it may be, but with all the weight of special knowledge and experience—and declines to make any effort to judge as to their respective claims on his attention. And, perhaps, it is worst of all when he accepts as the outcome of his own deliberate and unbiassed investigation of the subject, the involuntary repetition of acquired and inherited conclusions, *because they coincide with* his own mental tendencies, and are in accord with the opinion of other humane and respectable people.

In England the majority of working physiologists hold medical degrees, and many of them hold, or have held, important medical appointments. In the opinion of the laity, the twenty thousand medical men in the kingdom are all physiologists, and their several opinions on the vexed question of vivisection are all of practically equal weight. But the intelligent layman does not go to a country attorney for an opinion on a difficult case of Chancery practice; nor does he even ask an obstetrician to operate on him for cataract. From amongst all the registered members of the profession there might perhaps be gathered an absolutely considerable number of those opposed to vivisection; relatively to the whole, that number would be but small; and the ratio of opponents to supporters becomes smaller still, if we select for classification in this way, those whose knowledge, both of their profession and of the subject now under consideration, is specially noteworthy and most widely recognised. In estimating the importance of vivisection as a method of experimental research and its benefits, actual and potential, in relation to medicine and surgery, the opinion of those whose life-long work and experience have embraced both fields of observation, must be admitted to have a weight unattainable by others. Now, the opinion of the leaders of the profession—that is, of those who specially possess the double qualification just alluded to—is practically unanimous as to the real value and the great importance of vivisection. It is because of this—because this practically unanimous

expression of opinion comes from those who are recognised as being the men best qualified to judge the question in all its bearings—that the great mass of the profession at large—men, that is, whose duties and position do not allow them the means, and time, and opportunities to work out the details of the problem for themselves—accept the result, and are justified in doing so. Briefly, the case stands somewhat thus: The leaders of the medical profession, as honourable and learned men, highly skilled, both in the exercise of their calling and in their knowledge of practical physiology, are best qualified to judge as to whether vivisection is justifiable by reason of its conferring upon humanity at large boons which are, out of all proportion, in excess of the suffering which is entailed by its practice upon animals. The members of the medical profession generally are those best able to estimate the qualifications and the integrity of its leaders. The profession, as a body, accepts the conclusions arrived at by its leaders; and the general public, if it be too ignorant or too lazy to honestly work out the question for itself, might surely do worse than adopt the opinion which has been formed with such painstaking and deliberate care, and which is fortified by such credentials.

We are not now concerned with the vindication of vivisection, rather with the position which a great body of laymen allows itself to assume with regard to this question. We complain that so many permit themselves to drift into the attitude of violent, or at least decided, partisans, without having taken any conscientious pains to sift and weigh either their own arguments or those of their adversaries. If people at large could be induced to take the trouble of fairly judging for themselves, and if those who really cannot take it would accept only the views of men who have shown themselves possessed of the qualities requisite for deciding such a question, the profession would wait patiently and contentedly for the result. But the fact is that, while they will bow to the general consensus of the ablest theological or legal authorities on difficult questions of theology or law, the public seem unable to realise that physiologists, who devote their life and energies to their own special work, are at least entitled to a respectful hearing, when they state the methods which they have found most satisfactory, and point out the practical bearing of the results that have been already achieved. There are those who profess to have found no difficulty in realising a state of things in which two and two make five; under similar conditions we can imagine a man whose knowledge, experience, research, scientific caution, and judgment, were equal to those possessed by the greatest and most able of his opponents, and who, nevertheless, had reached the deliberate conclusion that under no circumstances was any form of vivisection either justifiable or useful. We might differ from him in his opinion, but we should honour such a man none the less; feeling that truth would suffer no careless wrong at his hands, and that he would not lightly speak evil of any one of her sincere disciples. But we would point out how easy it is for many men of noble heart and good intentions to clothe themselves with a fair show of tender tropes, and indisputably moral maxims, all neatly pieced together, and finished with a broad phylactery of virtuous phrases, and yet to hide within it all an incarnate selfishness—a selfishness that will not even take the trouble to find out whether that fair-seeming garment is alike on both sides. This state of things bears with peculiar hardship upon the general practitioner. In modern society he often owes no inconsiderable portion of the status which is accorded him to a reputation for something like encyclopædic knowledge. Upon all the more important scientific questions of the day he is assumed to entertain settled and definite opinions. He is, as we have already hinted, generally branded as a decided advocate of vivisection, and he is consequently regarded as fair game by all who chance to hold the contrary opinion. Now this is a very annoying position for such a man. If he be the intelligent and conscientious student, which we assume he is, he has probably, after long and patient consideration, formed his own conclusions on the subject, and has accepted the opinion expressed by those whom he knows to be specially qualified to give judgment in the matter; and he believes, let us say, that the practice of vivisection by men possessing the requisite acquirements, and carried on under such supervision as, while it shall not trammel the search for truth, will prevent all possibility of abuse, is a method of scientific investigation which is justifiable because it is useful, because it has already proved the means of gaining valuable boons for the human race—and for animals as well—and promises to continue to do so in the future; or possibly he holds the question still *sub judice*. But in neither case is he anxious to discuss the matter at the dinner table; to be involved in an endless string of explanations and discursive arguments with the philozooic lady whose knowledge of the subject is expressed, with the vague but witching tautology of her sex, in the phrase "Vivisection of a live dog;" and, above all, he does not want to "talk shop." So that when the enemy opens fire, he is tempted to reply "My dear sir," or "madam," as the case may be, and too often it is the latter—"we shall both, I trust, continue to be polite, but upon a matter like this we must also be precise. If I, understanding hardly a a note of music, should venture to criticise, say, the construction of a fugue of Bach, you would not consider my opinion entitled to acceptance, and would probably regard it as scarcely worth the trouble of refuting. I am not acquainted with the extent of your scientific acquirements, particularly in those branches of anatomy and physiology which are germane to the subject; if your knowledge is greater than my own small share, I will willingly learn of you; on the other hand, I will undertake, upon certain conditions, to coach you in these subjects, until we are able to meet on level ground, and there exchange opinions to our mutual edification and enlightenment. But if we begin by attempting to discuss the question from different levels, it can only end in one of us pelting the other with arguments, which will have no effect, because their true value will not be understood." And we doubt whether, under the circumstances, he could say anything more sensible.*

* Since this article was in type, the writer has had an opportunity of reading "Physiological Cruelty." It is a little book which can be heartily recommended as a calm, dispassionate, and able exposition of both sides of the question, devoid of technicalties, and quite within the comprehension of any intelligent person.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 22ND, 1884.

Sir ANDREW CLARK, Bart., M.D., President, in the Chair.

Thrombosis of Inferior Vena Cava.

MR. MANSELL MOULLIN read a paper on this subject, of which the following is an abstract; the patient being shown as a living specimen.

The patient was a man, aged 35, who was admitted into the London Hospital in August, 1883, for varicose veins and ulceration of the left lower extremity. He was employed as a paper-hanger; had been a trumpeter in the army, but had never had syphilis. There was no history of gout. A year and nine months before admission he fell down a staircase on to his back, cutting his right leg severely, and falling with his loins across the hand-rail. From the effects of this accident he was confined to bed for five weeks, his right leg becoming much swollen. While in bed, three weeks after his fall, he noticed that the veins in the lower part of the abdomen were enlarged, and from that time they have gone on gradually increasing in size and spreading in extent up to the present time. There does not appear to have been at any time either general anasarca or hæmaturia, judging from the statements made by himself and his friends. On admission, it was noticed at once that the abdomen was covered with great clusters of tortuous veins, which might be divided into three main groups—two on the left side, the one having its origin in Scarpa's triangle, the other just above the crest of the ilium; and the third on the right, behind, some four inches to the right of the vertebral column; and from these main groups great coils of enormously distended veins stretched upwards, gradually diminishing in size as they reached the thorax and could pour their contents into the superior epigastric, intercostals, and long thoracic veins. The right epigastric was but slightly enlarged in comparison, but in this as in all the rest the current was upwards in direction. The left limb was so swollen as only to be lifted with difficulty; the right, six inches less in circumference, was almost normal. In the abdomen was a large ill-defined mass lying in front of the vertebral column, most prominent opposite the umbilicus, and running down to the right of this a line along which pulsation and a systolic thrill and bruit could easily be ascertained. Besides this, in the large left lumbar cluster were a continuous thrill and an exceedingly loud bruit. There were no signs of aneurysm, the pulsation in the abdomen being distinctly not expansile; the lungs were emphysematous; the heart slightly enlarged and the aorta dilated; there were no hæmorrhoids, no varicocele to any extent, and no albuminuria. The diagnosis made was that of thrombosis of the inferior vena cava, with a clot extending down through the left iliacs to the femoral on that side, the ill-defined tumour in the abdomen being the plugged inferior cava, with swollen and œdematous tissue round it, the line of pulsation corresponding to some large abdominal vessel, probably the superior mesenteric displaced to one side. The thrombus could never have extended above the renal veins, but there is no evidence to show whether it originated in a small trunk and spread on till it involved the cava, ceasing where the renal veins poured in a large current, or started in the cava itself. There is, however, little doubt, judging from the time of its occurrence that it must be directly connected with the accident. Reference was made to a case published by Robin, in which violent exertion, while in a stooping position, produced the same result, and to other cases, which tended to show that complete obstruction of the inferior cava by tumours, or otherwise, need not of itself cause appreciable enlargement of the external veins or much œdema.

The PRESIDENT suggested that the case should be again brought forward to the Society at some future time, when further changes had taken place.

Charcot's Joint Disease attacking the right Elbow and Foot.

By Mr. R. CLEMENT LUCAS.—The patient was a man, aged 39, who came under notice last autumn, and was at that time exhibited at the Society. His father died of heavy drinking and consumption. His mother is still living, but suffering from dropsy and asthma. He is one of nine children, seven of whom are living. One brother was a cripple from right-side paralysis from birth, but lived to be 40. He denies having had syphilis, and there is no history of fits or insanity in the family. He has been much exposed, as a hawker, to wet and cold, and has drunk freely. About four or five years ago he became subject to rheumatic pains which shot through him. He has had neither girdle-pains nor gastric crises. For twelve or eighteen months he has had occasional numbness in his hands, especially the right, and has found a difficulty in buttoning his collar and in walking in the dark. Eight or nine months ago he had an attack of double vision, which lasted about a week, and then passed off. He occasionally felt giddy when starting to work in the morning, but was unconscious of any decline or defect in walking. About two years ago his right elbow became enlarged, but not very painful. He sought advice, and was treated with blue ointment. He has continued to work with it ever since. A few weeks before being seen, his right foot became somewhat suddenly enlarged, red and painful, and it was on this account that he came under treatment. The swelling extended from the malleoli to the bases of the metatarsal bones, and occupied the dorsum and sides of the tarsus. It was neither œdematous nor tender, but he suffered from aching pain beneath the head of the astragalus, especially after walking. The right elbow-joint presented a remarkable deformity. On the back of the ulna, two inches from the tip of the olecranon, was a rounded projection, about the size of half a Tangerine orange, two inches in diameter, and bony at the base. Between the head of the radius and the olecranon was another projection, sharp, prominent, and bony, apparently growing from the radius, and another prominence continuous with this between the head of the radius and the external condyle. These latter projections absolutely prevented all pronation and supination. A small outgrowth sprang from the inner side of olecranon, and projected beneath the internal condyle. In front of the joint, just external to the tendon of the biceps, was a rounded swelling an inch and a half in diameter, covered by muscles. Flexion of the elbow could be carried to the normal limit, but extension was arrested at an angle of 150°. The joint was free from pain. It measured about two and a half inches more in circumference than the other. The signs of locomotor ataxy were as follows:—He was unsteady when his eyes were closed; if told to touch his nose with his eyes shut, he often missed the mark; he had difficulty in walking in the dark and in buttoning his shirt-collar. His pupils were not contracted, but unequal, and insensitive to light; patellar reflexes were entirely absent. Mr. Lucas alluded to the liability there was for these cases to be mistaken for

osteo-arthritis. He thought it rare for the joint affection to be in advance of the ordinary symptoms of ataxy. More generally, the paralytic symptoms had existed some time before the joints suffered. Surgeons had been blamed for not recognising the disease. The symptoms, he thought, were sufficiently distinct, but the disease was not common among surgical out-patients.

Dr. BUZZARD thought that Mr. Lucas's case formed an apt illustration of the statement that the rarity of such cases may be explained by the failure of surgeons to recognise them as distinct forms of joint disease. Mr. Lucas himself had not been able to diagnose the case positively when he first saw it. No doubt the chief difficulty lay in the complete absence of ataxia which characterised so many of the cases. The case shown by himself that evening was one of short duration, in which ataxia was confined to the upper limbs; the patient, who was a carpenter, had first become aware of his illness from inability to use his saw in a straight line, or to strike accurate blows with his hammer. All other symptoms were present, the irresponsive pupil, the paresis of ocular movement, shooting pains and numbness, but the gait was not ataxic. The patient had been treated at two hospitals in London before applying for relief at Queen Square, and the joint affection had been presumably unrecognised as Charcot's disease. In the joint itself there was no evidence of any but the synovial tissues having become destroyed, and in this the case contrasted with that described by Mr. Lucas, in which there was distinct overgrowth of bone. It was usual for the ligaments to become affected early, extreme laxity of the joints being produced, which, in the case of the ankle, rendered the foot constantly liable to be thrown on its side in walking. Dr. Buzzard reiterated his belief in the connection between the joint changes, and some affection of the medulla oblongata. This localisation was arrived at, partly by exclusion, since almost all the other parts of the spinal cord might be diseased without giving rise to any such changes; and partly by the frequent association of gastric, laryngeal and intestinal crises with the progress of the disease. He further hinted at the possibility of the existence of some centre influencing the nutrition of the bony skeleton.

Dr. HALE WHITE referred to a specimen recently shown by him at the Pathological Society, taken from a dissecting-room subject, and stated that his own diagnosis of the nature of the changes had been fully confirmed by Professor Charcot, who had examined the specimen and pronounced it typical. Having recently had opportunities of seeing several living specimens of the disease, Dr. White was impressed with the difficulty of distinguishing between the various forms of arthritis, and quoted some remarks of Dr. Weir Mitchell, and of Professor Charcot to the same effect.

Dr. ALTHAUS thought that we were not as yet in possession of a sufficiently large pathological experience of the disease to warrant any theory as to its nature. In his own opinion, the cause should rather be sought in some lesion of peripheral nerves than in any lesion of centres. The symptoms of anæsthesia and analgesia, when present, and the trophic lesions, as evinced by herpes or other skin changes, all pointed in the same direction.

Dr. BUZZARD mentioned that in many cases where the peripheral nerves had been examined, they had been found quite healthy.

Dr. MOXON, in response to the President's invitation, stated that he was himself inclined to be sceptical as to the part played by the nervous system in producing this form of arthritis. Although he must look with respect upon the convictions of Drs. Charcot, Buzzard, and others, still his own experience of many cases of locomotor ataxy, and very few of Charcot's disease had led him to look upon the coincidence of arthritis with spinal cord disease as only an occasional one. Before assuming that a definite connection exists between the two, we require a far greater amount of evidence, and especially statistical evidence, to show the frequency of their simultaneous occurrence. If, as suggested by Dr. Buzzard, there was a controlling lesion for the nutrition of the skeleton, it became difficult to understand why one joint alone should be marked out for destruction. With respect to gastric crises, he had been often struck with the frequency of cases amongst over-worked patients, school-teachers and others, presenting symptoms not distinguishable from those described by Charcot, but certainly not associated with any definite form of brain or spinal cord disease. He was inclined to think that the over-observation of ataxic persons sometimes led to inaccurate conclusions, many symptoms common alike to the ataxic and the non-ataxic, being specially noted and recorded as "epiphenomena," obtained an importance which they did not deserve.

The PRESIDENT expressed a belief that, with more complete statistics, it might be found that the joint affection at times occurred in association with cerebral disease.

Mr. CLEMENT LUCAS, in reply, explained that the diagnosis of his case had been rendered difficult by the peculiarities of the changes in the joint, but, from the first, the case was unlike any well-known joint affection, from the peculiar form of the swelling of the ankle and the marked absence of pain. He was himself quite convinced of the distinction between these cases and those of any other form of arthritis.

Dislocation of one of the Semi-lunar Fibro-Cartilages of the Knee-joint.

Mr. NOBLE SMITH communicated this case, with remarks, as follows:—The left knee was first injured sixteen years ago (1867) by a fall. Great pain was felt, and while being carried home the patient was upset, the knee again twisted, and the intense pain was immediately relieved. This history was considered as characteristic of displacement of one of the cartilages. The patient was unable to move for many months, rest and local applications being prescribed. After nine months walking was commenced again. The subsequent history was that of repeated injury from trivial causes, and a continued state of weakness of the joint, with discomfort or pain during movement. The same kind of treatment was always prescribed, and in the course of weeks or months after each accident the patient would gradually recover sufficiently to be able to get about again, but always with difficulty and in danger. On November 11th, 1882, this patient was first seen by me. A stiff knee-cap was being worn, and any locomotion was extremely difficult. *Rest as complete as possible* had lately been again recommended, and the advice was being carefully followed. The knee was slightly flexed, and could not be moved without pain being produced. The internal cartilage of the left knee was felt to project slightly beyond the upper border of the tibia. Upon pressure being applied to this protrusion while the leg was flexed and extended repeatedly, the cartilage was felt to slip back, after which the patient walked round the room perfectly naturally, and felt a relief which had only once been experienced since the first occurrence of the accident A pad was strapped over the place where the cartilage had protruded. During the next few weeks there was a tendency to relapse, but by perseverance with the treatment, the joint was gradually worked into a natural condition. An apparatus was made, which, while it permitted flexion and extension of the leg, prevented lateral motion and twisting. Walking exercise was recommended from the first, provided no pain was felt. This patient has remained quite well up to the present time, December, 1883. Several other similar cases had been met with by him. Great care in forming a diagnosis was necessary. This displacement, which was first described and the appropriate treatment devised by Mr. Hey, of Leeds, was to be distinguished from inflammatory disorders and the presence of loose cartilages. The variety of the conditions which might occur were described by Hamilton. Bounet, of Lyons, experimented upon a dead body, and produced displacement of the inner cartilage, and sub-

sequently reduced the dislocation by extension. The experiment was frequently repeated with a similar result.

Mr. Howard Marsh disclaimed the discovery of the special apparatus, attributed to him by Mr. Noble Smith, the credit belonging entirely to Sir James Paget. Referring briefly to the subject of the paper, he pointed out the greater liability of the external semi-lunar cartilages to displacement. One common cause for the lesion was to be found in football, when a vigorous kicking movement was made without striking the ball fairly, and so failing to meet with the expected resistance. In one such case a small body had been removed from the knee-joint, which proved to be a piece of the semi-lunar cartilage completely torn off. He would insist upon the value of mechanical treatment in these cases, and he exhibited to the Society some photographs of apparatus successfully employed at St. Bartholomew's Hospital.

Mr. Tyson (Folkestone) related a case under his own care, in which there had been displacement of the internal semi-lunar cartilage for ten years, frequently recurring, and often giving rise to great difficulty in reduction. The patient was only safe in the perfectly straight position. The best means of reduction had been found in abduction and rotation outwards, as in sitting cross-legged.

Mr. Lucas mentioned that in all the cases that he had met with, the external semi-lunar cartilage had been displaced, and to the outer side. One case had made a good recovery in plaster of Paris.

Mr. Noble Smith, in reply, observed that in his own experience of cases the internal cartilage was more usually displaced, and generally as the result of some sudden movement. He did not agree with the treatment by complete rest, but advocated movement in a properly constructed apparatus.

Pulmonary Regurgitation.

The President drew attention to the living specimen exhibited by Dr. Fowler, and suggested that a small committee be appointed to investigate and report upon the case. He nominated Drs. Moxon, Douglas Powell, and F. Taylor to co-operate with Dr. Fowler for the purpose.

The following specimens were also exhibited:—

Charcot's joint disease, by Dr. Buzzard.

Rheumatic nodules on the finger, by Mr. Godlee.

Congenital hypertrophy of leg, by Mr. C. J. Symonds.

Excision of the patella, by Mr. Lucas.

Anomalous affection of certain bones and joints, by Mr. W. Morrant Baker.

Continued profuse sweating of upper half of body, by Dr. Stephen Mackenzie.

Obstruction of vena cava, by Mr. Mansell Moullin.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, February 26th, 1884.

Richard Barwell, F.R.C.S., Vice-President, in the Chair.

At the ordinary meeting on Tuesday last, two papers were read and discussed. The following are the abstracts and discussions:—

Neurectomy of the Second Division of the Fifth Nerve.

By Thomas F. Chavasse, M.D., C.M., Surgeon to the General Hospital, Birmingham. — *Case* 1. — A man, aged 50. Intractable neuralgic pains extending over a period of fourteen years. Talking and movements of the jaws gave rise to painful paroxysms, which were exaggerated in cold, wet weather. The pain always commenced in the situation of the right upper molar teeth; thence it passed upwards to the cheek, to the temporal fossa and parts around the orbit, and produced a profuse flow of tears. He had endeavoured at intervals to follow his occupation as a labourer, but for six months before admission to the General Hospital, Birmingham, had been quite incapacitated. October 3rd, 1882, Carnochan's operation, modified as to the skin incisions, was performed, and by removing portions of the anterior and posterior walls of the antrum by trephines, the infra-orbital nerve was traced back into the spheno-maxillary fossa, and removed just anterior to the foramen rotundum, together with Meckel's ganglion. No constitutional symptoms followed the operation, and by October 16th the wound was healed. The patient has continued to be free from pain ever since, and has resumed his old occupation. *Case* 2.—Man, aged 47, had suffered from intractable neuralgia for eleven years. Pain excited by speaking, masticating, and walking. Always commenced in the situation of the upper molar teeth of the left side, and latterly was so severe that relief could only be obtained by lying quietly in bed. February 9th, 1883, similar operation as in previous case. Cavity of antrum was very deep, and the hæmorrhage profuse, so that, although the posterior dental nerves were seen and divided, Meckel's ganglion was not removed with the nerve. The wound healed in a fortnight, and the patient was able to take solid food. The immediate relief from pain was not so complete as in the case in which the ganglion was taken away, but the patient is now in full health. The opinions of Carnochan and Billroth were quoted as being favourable to the removal of the ganglion when possible. In both cases the writer thought that the more radical operation of neurectomy held out better hopes of obtaining relief than either neurotomy or nerve stretching. Statistics showed that after this operation relief was generally obtained for longer or shorter periods, and no fatal result had been recorded. Attention was directed to the methods of operation introduced by Professor Lücke, of Strassburg, and by Professor Lössen. Cases were quoted in which Braun had successfully operated by the plan of the latter, and an instance was given in which Reyher, of St. Petersburg, had tied the common carotid artery before proceeding to the other steps of the operation.

Mr. Walsham said that he had had some considerable experience in the operative treatment of these cases of so-called epileptiform neuralgia or incurable tic, and had within the last six weeks performed Carnochan's operation for the removal of Meckel's ganglion. The patient came under his care at St. Bartholomew's Hospital, about the end of last December. He had suffered for upwards of fourteen years from epileptiform neuralgia of the most intractable character. He had formerly been a patient under Dr. Buzzard and Mr. Adams, and had had the supra-orbital and infra-orbital nerves stretched on several occasions. He had at first received some relief from these operations, but latterly the neuralgia had returned, if possible, in a more severe form than ever. As his (Mr. Walsham's) cases which he had treated by nerve-stretching had been all attended with success, he thought it right to again stretch the supra and infra-orbital nerves. He accordingly cut down upon them, but found that the tissues were so matted together as the result of the previous operations, that he was unable to isolate either nerve. He accordingly passed an aneurism needle under the cicatricial tissue, at the situations where he conceived the nerves ought to lie, and endeavoured to stretch it, but he could not convince himself that it yielded to any appreciable extent. Suffice it to say, that upon the patient recovering from the chloroform, he had a very severe paroxysm, and in short, received no benefit whatever. On more closely questioning the patient, it was found that, although he said the pain began in his cheek, and darted upwards over the head, it was really located in the gums, in the region of the molar teeth, which had previously been extracted, *i.e.*, in the posterior dental nerves, and shot upwards towards the back of the orbit. Mr. Walsham then proposed the removal of Meckel's ganglion—an operation to which the patient readily consented, provided that he could be promised a fair prospect of relief. Mr. Walsham had

accordingly written to Mr. Chavasse, who had very courteously had not only informed him of the success of his case, but had also given him several valuable hints which proved of much use subsequently. The operation was performed on January 17th, very nearly in the way described by Mr. Chavasse. The only modifications to which Mr. Walsham thought it worth while to call the attention of the Society, were the following:—1. That, instead of trefining the posterior wall of the antrum before cutting away the lower wall of the infra-orbital canal, as had been done by Mr. Chavasse, he first removed the lower wall of this canal, so that should hæmorrhage have ensued on trefining the posterior wall of the antrum, as in Mr. Chavasse's cases, this part of the operation, viz., removal of the lower wall of the canal, might be completed before the parts became obscured by blood. The opening of the canal was the most tedious part of the operation. None of the forceps at command were suitable for the purpose. He had, therefore, on the chance of having a second case, had a forceps made by Messrs. Arnold. With these he could accomplish in two or three minutes, what it had taken him fully ten to do without them. 2. He advised, that in removing the posterior wall of the antrum, the greatest care should be taken not to injure the periosteum lining the spheno-maxillary fossa. If this were done, there need be no fear of hæmorrhage, as the vessels lay on the fossa side of the periosteum. He had avoided injuring the periosteum, by cutting through the posterior wall of the antrum with the trefine only at one spot, and then having separated the periosteum from the bone, had fully exposed the fossa by use of bone scissors. There was no hæmorrhage during this part of the operation. 3. The whole length of the superior maxillary nerve being exposed, it was seized with forceps, and stretched with a force probably sufficient to make a distinct impression upon the Gasserian ganglion, if not on the trunk of the nerve beyond. It was then divided immediately external to the foramen rotundum, and removed along with the ganglion, the branches of which had been previously divided. Mr. Chavasse, in his letter, had advised the use of reflected light. The operation was performed with the laryngoscopic mirror on the forehead; with its aid the antrum, though deep, was kept fully illuminated, and the various steps of the operation could be followed with exactitude. Mr. Walsham strongly recommended its use to any future operator. The patient made an excellent recovery. He slept well the night afterwards, better than he had done for months before. He had no constitutional symptoms. He was up and about the wards in a few days, and the wound healed kindly, and he was now at the Convalescent Home at Highgate. He had had no pain since the operation. Mr. Chavasse had suggested that neurectomy and removal of the ganglion was a better operation than nerve stretching. Mr. Walsham ventured to think that both were excellent in appropriate cases. He had now had four cases of the most obstinate epileptiform neuralgia in which he had performed nerve stretching. In the first he had stretched the infra-orbital only; in the second, the auriculo-temporal and inferior dental from within the mouth; in the third, the inferior dental only from within the mouth; in the fourth, the infra-orbital and inferior dental. The first case was done in the early part of 1879. There had been no return of pain when last heard of a year ago. The second and third were stretched last May. The fourth last November. In none of these had there been any return of the neuralgia. In all, the nerves had been stretched from their distal as well as from their proximal ends. Before the fifth case came under notice, Mr. Walsham had hoped that we had at length found in nerve stretching an effectual remedy for this distressing affection. But should this fifth case be regarded as a failure? On closer enquiry it was found that the pain, although said to be in the cheek, really began in the gums. Was it not possible, therefore, that the posterior dental branches had been at fault throughout, and that both Dr. Buzzard and Mr. Adams, as Mr. Walsham confessed himself to have been, were misled by the patient referring the pain to his cheek? The success attending Mr. Chavasse's cases was most encouraging. As to the result of his own case, it was of course too early to speak, but he hoped as the operation for the removal of Meckel's ganglion might still be said to be on its trial, that on some future occasion, when sufficient time should have elapsed for forming a reliable judgment as to the permanency or not of the relief, to briefly publish the notes and subsequent history of the case.

Mr. Bowlby said that an examination of the deepest part of the excised nerve showed a considerable increase of fibrous tissues, arranged irregularly and not after the manner of the fibres of the normal perineurium; this fibrous tissue was probably inflammatory in its origin. The nerve bundles were compressed, the nerve tubules, in some places, were entirely degenerated; in others, the white substance of Schwann was much diminished, and the nuclei of the sheath multiplied. It is doubtful whether this condition was originally the result of inflammation spreading along the dental nerves, and thus causing the neuralgic pains, or whether it was due to the operations that had been practised on the infra-orbital nerve at various times. Further examination in other cases would be required, in order to clear up this point.

Mr. Morris thought the Society was indebted to Mr. Chavasse, not only for bringing forward this operation, but also for cases, sufficiently long after the operation, whereon to base an opinion as to its real value. The future, however, could alone decide whether the cases were really cured. The same might be said of neurectomy and neurotomy: the good results being usually very temporary and very fleeting. Trousseau had stated that, in his own experience, a permanent success had never been attained. Mr. Morris reviewed the literature of nerve stretching, and showed how little had been attained by this plan in tetanus; he argued that the successful results were quite as much due to drug treatment, which had been simultaneously employed. These intractable neuralgia cases frequently had periods of remission irrespective of treatment. The transference and reflection of pain along branches which were not themselves diseased, he said, was an argument against such operations being successful. Attention was directed also to the vast importance of removing all possible sources of peripheral irritation, such as carious teeth, and alveoli, cicatricial tissue, &c.; good could often be obtained, he thought, by a judicious use of morphia or other sedatives.

Mr. Treves thought that a permanent cure was not very likely to be obtained, and all that could be expected was a longer or shorter period of relief.

Dr. Buzzard had looked up his own notes of the case to which Mr. Walsham had referred, and found that they justified the observation which he (Mr. Walsham) had made as to the probable affection of the posterior dental branches as the seat of the lesion. He found that the man had suffered greatly with pain in the roof of the mouth, which was a very unusual situation in cases of trigeminal neuralgia. Would such an operation as the one described have any effect, he asked, in curing pain along the distribution of the inferior dental. The proceeding appeared to him, as a physician, a rather formidable one; but he could quite understand a patient, the subject of such agonising pain as was experienced in these cases, being glad to submit to anything that offered even only a chance of relief.

Mr. Walter Pye had had two cases of nerve stretching, and agreed that one could never feel quite sure that a cure had been effected. His own cases had had complete relief for twelve or fifteen months, and then began to suffer again.

Mr. Chavasse replied to the remarks of the various speakers, agreeing for the most part with their observations.

A Case of Amputation of the Arm and Scapula for Ossifying Sarcoma—Recovery.

By Christopher Heath, F.R.C.S. — The patient, a lad of sixteen, was admitted into University College Hospital July 2nd, 1883, with a large sarcomatous tumour of the upper arm and shoulder. Two years before he had noticed that the upper end of the right humerus was slightly larger than that on the other side. It had gradually increased in size, but much more rapidly during the last six months. In January, 1883, the

patient was in St. George's Hospital, where Mr. Holmes proposed to amputate, but the patient declined, and went home to Cornwall. The shoulder was obscured by a roughly pyramidal swelling, the base being at the axillary border of the scapula, and the apex at the middle of the humerus. The posterior edge of the growth was rounded, and its outer surface was divided by a depression into a lower, prominently rounded half, and an upper, more flattened mass. The growth involved the scapula, and completely fixed the shoulder-joint, but the whole mass with the scapula moved freely over the thorax. The skin was not broken, but was tight, and cracked over the posterior part of the growth, where it was of a dark-red colour. The tumour throughout was hard, and bossed here and there. Its circumference at the most prominent point was 24 inches. The glands in the axilla and neck were not enlarged. The chest and abdomen were healthy. On July 4th, 1883, Mr. Heath made an oval incision as for amputating at the shoulder, and, having stripped back the skin, cut upon the position of the shoulder-joint, and removed the arm, necessarily leaving a large mass of growth attached to the scapula. The axillary artery was tied with hemp ligature, and the neck of the scapula, with the glenoid cavity and inferior border of the bone, was sawn off. Mr. Heath next removed the scapula, first dividing the clavicle at its outer third, and then isolating the posterior border of the scapula. The wound was dressed on second and fourth days, and the patient made an uninterruptedly good recovery. The highest temperature was 104° on the eighth day. He was discharged on August 30th, being only 59 days in hospital. The part removed consisted of a large mass of ossifying sarcoma surrounding the upper end of the humerus, and firmly united to the scapula and clavicle, the growth extending down the humerus to the junction of the upper and middle thirds. The scapula itself was but slightly affected, the growth extending backwards for a short distance around the neck of the bone, and down the axillary border. The growth extended into the subscapularis, teres minor, and, slightly, the infra-spinatus muscles. The cut end of the clavicle was healthy. Microscopically, the growth was found to be a sarcoma of mixed small cells and oval corpuscles, with extensive ossification, in the shape of bony spicules, running through the tumour. In none of the spicules were Haversian canals to be seen, but lacunæ were normally developed.

The patient was shown.

Micro-Organisms.

Dr. Heneage Gibbes showed, in the ante-room, a number of the different forms of putrefactive bacteria :—A section of diphtheritic membrane, showing two forms of micrococci, one large in groups, the other much smaller in masses. A section of human spleen from a case of tuberculosis, showing large micrococci in groups; similar organisms were found in the lungs and liver of this case. Sections from the livers of two pigs, which had died of the purples or "red soldier." These were sent to Dr. Gibbes by Mr. Crooke, of the Leeds Fever Hospital. Sections of these livers were full of bacteria, but the forms were quite different in each. In one liver the bacteria consisted of short rods not joined together, in the other they were very long and slender. Section of kidney from one of these cases showed the vessels full of a form quite different to those in the liver. Stool from a case of infantile diarrhœa, showing organisms very similar to those in the specimen of rice-water stools, sent by Professor Straus. Very large organisms from the stomach in a case of carcinoma of pylorus—spirilla, vibriones, various forms of bacteria in chains, micrococci from putrifying animal matter in water. Section of mesenteric gland, showing the so-called typhoid bacillus. Human sputum from cases of tuberculosis; one specimen showed different forms of bacteria in the field of the microscope, and this with an oil immersion lens magnifying 600 diameters. These specimens were shown with Messrs. R. and J. Becks' new pathological microscope, which they have made from Dr. Gibbes' designs.

The Secretary read the report on the cholera germs, which is printed in another part of the journal.

The Society then adjourned.

HARVEIAN SOCIETY OF LONDON.

Thursday, February 21st, 1884.

George P. Field, M.R.C.S., in the Chair.

Wet-Packing in Scarlatinal Dropsy.

Dr. Day read notes of a case of scarlet fever followed by nephritis, convulsions, and death, temporarily relieved by wet-packing. The patient, a boy, aged seven, was first seen by him on October 1st, 1883, when he was covered with a bright scarlet rash, having been apparently in his usual health the previous day. The throat, cervical glands, and kidneys, were severely affected, and albumen and blood appeared in the urine. On the 18th of October scarlatinal dropsy set in, which almost disappeared under wet-packing. On the 20th there was diarrhœa and vomiting. On the 23rd the patient was seized with convulsions, and died. Attention was drawn to the extreme brightness of the rash which was distinct on the tenth day of eruption, and to the dropsy which the author did not consider usual when the skin was so much involved. He thought the wet-pack was of great advantage in exciting free cutaneous action, and in relieving the anasarca. He also alluded to cases of scarlatinal dropsy without albuminuria, and quoted several authorities on the subject.

The President, in commenting on the paper, referred to the frequency of suppuration within the tympanum after scarlet fever, and to its treatment by early paracentesis.

Dr. Mahomed called attention to the present rarity of post-scarlatinal dropsy, as compared with former returns; at the Fever Hospital hardly more than two or three cases were recorded in the year. This result he attributed to the early treatment of the nephritis, none being more successful than sharp purging, and leeches to the loins. He bore testimony to the usefulness of Dr. Oliver's test-papers (mercuric iodide) as a ready means of proving conclusively the absence of albumen from any urine.

Dr. Cleveland insisted on the therapeutical value of the perchloride of iron in cases of hæmaturia.

Prognosis in Structural Diseases of the Heart.

Dr. Broadbent read an important paper on Prognosis in Structural Diseases of the Heart, in continuation of the subject of the recent Harveian Lectures, in which prognosis in valvular disease had been mainly considered. The paper dealt with the conditions of "Fatty degeneration of the Heart and of Cardiac Dilatation" in an exhaustive manner, which does not admit of any adequate report being furnished here. It is understood that the paper will be published shortly. An able discussion, in which Dr. Stephen Mackenzie and Dr. Mahomed took part, was followed by a reply by Dr. Broadbent, and the meeting was adjourned.

ABSTRACTS AND EXTRACTS.

THE PRESS ON THE ROYAL COMMISSION ON THE HOUSING OF THE POOR.

The *Times* maintains that it is to London that the chief attention of philanthropic reformers must be turned. It is there that the entire problem presents itself in its hardest and most complicated form. If an answer can be found that will suit the case of London, the difficulty will have been in effect solved. That the thing can be done and will be done the *Times* fully believes. The social question involved is too grave and too far-reaching in its consequences for society to dare to

be indifferent about it. The facts, it may be said, lie on the surface open to all eyes. It needs no expert to discover them. It will be the office of the Commission to bring them, as it were, to a single focus, and to present them as they require to be seen if their aggregate importance is to be judged. That the dwellings of the London poor are defective in sanitary appliances is, Lord Salisbury points out, a very small part of the case. Proper drainage and proper water supply can be demanded under the existing law, and if they are not granted it is proof only of a negligence of duty for which publicity may be the sufficient cure. To find house provision for the multitudes who are at present in want of it will be a much more difficult matter. Not among the least of the impediments reformers of the evils have to encounter is the necessity of educating the victims to appreciate the intensity of the wretchedness of the hovels ironically called their homes.

The *Morning Post* believes that there is a fixed resolution that something should be done in the interests of the poorer classes on a scale far exceeding anything previously contemplated. Before, however, any great or comprehensive scheme is formed, it is absolutely essential that materials far more voluminous than those now at our command, shall be collected and turned to account. Hitherto, the object of legislation in respect to the housing of the poor has almost exclusively been to improve their sanitary condition. But the far more comprehensive problem of preventing overcrowding, and enabling the poor to rent tenements which will permit them to live under conditions that do not of necessity foster vice and crime, is still untouched. The task which the Royal Commission must seek to accomplish, will be first to call abundant evidence as to the conditions under which the poor live, and then to recommend to the Legislature, if possible, some means by which those conditions can be considerably ameliorated.

The *Daily Telegraph* says, that what is wanted to be known is the localities in which this overcrowding exists, and how many of those who are crowded together are forced to dwell in these localities. One result of such enquiry would be to ascertain how far the existing evil could be reduced by a development of the facilities afforded by cheap railway trains; another result would be to determine whether larger building operations would be necessary, and, if so, in what districts and at what cost they have to be carried out. Lastly, there remains the difficult question, by whom the work should be paid for.

The *Standard* admits that the appointment of the Royal Commission will cause some delay in the introduction of measures of amelioration; but it is not sure that delay, even in a case of such grave necessity as this, is wholly to be deplored. No one will question either the capacity of the Royal Commissioners for their work, or their sympathy for the class whose interests are concerned in the enquiry. From whatever point of view the Commission is looked at, it must be pronounced to be a strong and eminently representative body, whose decisions will bespeak the confidence of the public.

The *Spectator*, in a very thoughtful article, says that the housing of the poor is exactly the subject for a Royal Commission. It bristles with difficulties, but for the most part they are not difficulties which involve principles. Commissions commonly represent the average good sense of the public, and any doctrine that is very novel and very startling comes in for nothing more than a complimentary reference in the report. The *Spectator* holds that in this matter common sense is a much better adviser than heroic philanthropy. What is most of all wanted is first a large assemblage of facts, and next a separation of the several classes of facts. There is all the difference in the world between the inability to get a decent lodging which comes from absolute poverty, and the inability which comes from relative poverty. A Royal Commission will be able to give full consideration to the points of difference, to trace them to their ultimate causes, and to make recommendations which shall go beyond plausible generalities. The *Spectator* is not quite sure whether the kind of commission it is apparently intended to appoint is in all respects the best.

The *Guardian* says the Royal Commission will have to ascertain why the remedies, which legislation has provided for imperfect sewage, bad repair, and unhealthiness of position with respect to other houses, have been so inefficient. As to the need of investigation into the housing of the poor in villages there can be no question. The only doubt is whether the conditions of the enquiry in town and country are not too distinct to make it profitable to handle them by the same Commission.

The *Scotsman* contends that there are Acts of Parliament enough in existence already; and if they were consistently and peremptorily enforced, there is no doubt that improvement would be more real and more rapid. In short, the state of the case is not that legislation is defective, but that administration has broken down; not that Parliament has been negligent, but that Local Authorities have culpably failed to do their duty. The labours of the Commission may be looked forward to, not with less, but with greater hopefulness, because other influences are at work, from which, more than from direct legislation, improvement may be expected.

SURGERY.

HYDROCELE.—The *New York Medical Journal*, December 22nd, 1883, publishes some observations by Dr. Robert Abbe on this subject. He does not differ from other writers as to the proportionate frequency with which the several forms are met with in practice, but directs attention to some points of interest. The "congenital" and acquired hydroceles of infancy would probably be cured by nature, but parental anxiety often demands some interference; they usually yield readily to mild stimulation (*e.g.*, an "evaporating lotion"—which is, practically, always bound on with the clothing) and to a more nourishing diet or tonic treatment. If of long standing, they commonly yield to puncture; this is best performed by holding "three or four surgical needles side by side between the finger and thumb, and, while making the scrotal sac tense, rapidly repeating the puncture stroke, pricking as many as 30 or 40 points;" the fluid quickly escapes into the cellular tissue, whence it is rapidly absorbed, and some escapes through the skin, aided by gentle squeezing. Aspiration is simple, and, in time, effective; but must usually be frequently repeated. The seton is effective; but, unless removed at just the right time—say after 36 hours—it will set up a disagreeable suppuration of the sac necessitating incisions. In the case of one child, whose hydrocele had been frequently aspirated, a cure took place only after circumcision for phimosis and preputial adhesions, and then rapidly. In young children (six months to two years) the tumour has disappeared under Pot. Iod. gr. 2, t. i. d., given for two or three weeks. In the hydrocele of adults, Dr. Abbe has almost invariably found an induration of the epididymis, either as a hardness of the entire body, or of the globus major or minor alone; this is, of course, only to be noticed after tapping. He has found encysted hydroceles exclusively in old men from 50 to 70 years; he differs from Curling in asserting that in this variety the cure by injection of iodine "is almost certain." As regards curative treatment in adults, he has found iodide of potassium efficient in cases where, after a single tapping, well marked induration of the epididymis was found to exist—although there might be good reasons for negativing syphilis. Injection of the sac with iodine, if rightly used, is a competent curative method in most cases; there is always more or less shock, the pulse falls 20 to 30 beats for a few minutes, there is usually some pallor, and a good deal of pain in the course of the vas deferens. Dr. Abbe would not use this method in a patient with weak heart. The injection of ʒj deliquesced crystals of carbolic acid—the scrotum having been previously well greased—is "probably the best method of the radical cure of hydrocele." It produces no shock, is almost always painless, the pulse does not vary, a more *plastic* inflammation appears to be set up, and after the operation the patient usually continues at his work. Only one man thus treated complained of pain, and he for three minutes said his "testicle felt as if it was in a frying pan." Carbolic acid poisoning has never followed injection. In the course of over 150 cases, representing, perhaps, 500 tappings, the only serious result occurred in the case of an old and intemperate patient, in whom a simple tapping, without injection, was followed by phlegmonous cellulitis and fatal

exhaustion. Dr. Abbe makes no mention of ergot, which, in the form of the liquid extract, has recently been advocated as a painless and efficient fluid for the cure of hydrocele by injection.

"Catheter Fever."—In a recent clinical lecture on urethral and bladder difficulties delivered in the New York Hospital, Dr. R. F. Weir remarks that "this is not an unknown disease at all; surgeons are constantly witnessing such ill effects of the introduction of the catheter . . . . in people who have had trouble with the prostate, and variable, incomplete, retention of urine for a number of years . . . Under the head of cystitis, pyelitis, and 'surgical kidney,' with or without appreciable abscesses, may be grouped clinically the severer symptoms producible by the introduction of an instrument into the bladder of an old or elderly man. This 'catheter fever' is something which every one of you will run against sooner or later, and . . . it is more apt to occur the longer the prostatic trouble has existed. This is a strong reason for teaching elderly men so affected to use the catheter early." On this point his teaching is more emphatic even than Sir H. Thompson's. He urges the necessity of teaching an old man to use the catheter regularly, so soon as difficulty in passing water is recognised. The patient, indeed, will object to what seems to him only a needless annoyance, and "you will find much difficulty in leading your patients to follow your advice; but if you do so, you will anticipate pathological change, and save them a good deal of subsequent trouble." In order to avoid this "catheter fever" in cases of this sort which have continued for several years, or in those where the patient is attacked with retention, Dr. Weir advocates the withdrawal of only half a pint of urine in the first instance, drawing off a little more at each subsequent catheterisation; but it is better still to "let the man pass what water he can in your presence, then introduce the catheter and empty the bladder; but do not leave it in its collapsed condition, rather throw into the bladder a quantity, equal to one-third or one-half of the urine withdrawn, of a solution of carbolic acid (one in 100), or of boric acid (℥ j to a pint), or, best of all, mercuric chloride (one in 5,000)." The quantity thus injected is to be gradually diminished on successive occasions, until the bladder gets used to its contraction. The patient should also be kept to the house for a few days, until tolerance of the instrument is fairly established. "Before using the catheter, pass a carbolic acid or corrosive sublimate solution through it . . . . and, so far as possible, introduce the catheter full of this solution, in order to guard against the entrance of air into the deeper urethra; on withdrawing it, pinch its end, and let it thus come out full of fluid. Use iodoformised oil (gr. v. to ℥j.) to grease it with, rather than carbolised oil, which is inert."

A Simple Operation in Facial Neuralgia.—Under this designation Dr. Heustis, Professor of Surgery in the Medical College of Alabama, describes an operation which he performed on a gentleman above 70, who was in good health in all other respects except that he suffered from severe facial neuralgia, affecting both the infra- and supra-orbital nerves. As the patient had become much weakened by the severity of the pain and his inability to eat his food, it was deemed desirable to render an operation performed upon the infra-orbital as simple as possible, consistently with its efficiency. "Therefore, discarding Carnochan's operation of trephining the antrum, and following up the nerve beneath the orbit and removing it, and Langenbeck's slighter one of dividing the nerve with a tenotome, and drawing it out through the infra-orbital foramen, I merely cut down upon the foramen, and with a fine steel drill, such as dentists use, improvised of piano-wire, drilled out the nerve in its entire length, as far back as the spheromaxillary fissure." The relief obtained was immediate and complete; and had so continued two months after the operation.—*Philadelphia Medical News*, December 8th.

Urethral Injections.—M. Aubert, Surgeon to the Antiquaille, Lyons, observes (*Lyon Médical*, February 10th) that attention is not sufficiently paid to the fact that the urethra is divided by the subpubic sphincter into an anterior and posterior portion; and that by too forcible injection this sphincter is forced, and the injected substance reaching the posterior urethra may thus excite much mischievous action. In fact, it is only under surgical superintendence that the posterior urethra should ever be injected at all. To prevent the mischief, M. Aubert takes a small caoutchouc tube of much less calibre than the urethra, and of from ten to twelve centimetres in length, introduces it into the urethra, and fixes the nozzle of the glass syringe to its free end. The injection is then made, with the orifice of the urethra closed. In this way the medicament is brought into contact with the end of the anterior part of the urethra, and is not impelled with sufficient force to reach the posterior urethra; and as the liquid returns by the side of the tube, the parts around become bathed with it.

GENERAL CORRESPONDENCE.

THE DEBATE ON CHOLERA.

[To the Editor of the Medical Times.]

Sir,—Your contributor, in the note appended to my letter in the *Medical Times and Gazette* of 23rd inst., first admits the error he had fallen into in his comments on "The Debate on Cholera" at the Epidemiological Society, in attributing to me opinions regarding small-pox and scarlatina which are not to be found in my letters in the papers of 4th and 11th August, 1883, and afterwards proceeds to justify himself as having written from memory, and in holding me accountable for opinions put forth by another. I have yet to learn that one who ventures to write from memory can claim to be excused from being equally careful as to facts as other men; and I entirely dissent from being held responsible for the opinion of others, on no better ground than your contributor's haziness of memory.

The passage in the leading article on "Credulity, Scepticism, and Agnosticism in Science," in the *Medical Times* of July 21st, to which I drew attention, after alluding to Dr. Cuningham's statement, that there is no evidence that human intercourse, &c., causes the spread of cholera, proceeds, "If so, why has it in Europe, and from Europe to America, invariably followed the great routes of trade? Why has it, in countries which have direct communication by sea only with others, when it is endemic or epidemic, invariably made its first appearance in those seaport towns which lie in the routes of such intercourse, and as constantly among persons just arrived from infected parts abroad?" With reference to this, I suggested to the editor that he had overlooked the epidemic of 1873 in the United States, which commenced at New Orleans, and the outbreaks at Southampton and at Theydon Bois, in this country, in 1865, in all of which able investigators, after a searching enquiry, admitted no trace of importation could be made out; and in all the early cases, seen in persons who had not been out of the country. Your contributor's reply to this, appended to my letter in the paper of August 4th, is—"All that Mr. Lawson's letter proves is what nobody denies, that in certain cases it was not possible to discover the origin of the outbreak in importation," followed by some other remarks, one of which on the nature of the disease at New Orleans was disposed of in my letter in the *Medical Times* of 11th August, and the remainder are beside the point at issue. Now that your contributor has acknowledged himself the author of all the articles on this question, and admits it was not possible to discover the origin of these outbreaks in importation, and that the first cases were in persons who had not arrived from infected ports abroad, I have no doubt the readers of the *Medical Times*, like myself, will be curious to learn how he came to write the passage quoted above from the paper of 21st July.

ROBERT LAWSON,
Inspector-General of Hospitals.

London,
26th February, 1884.

[Mr. Lawson now admits, and in the face of our quotation it is not easy to see how he could do otherwise, that we have not in any way misrepresented Dr. Cuningham's views on contagious disease in general; and he himself now disclaims all sympathy with them, except as regards cholera. Had Dr. Cuningham limited his scepticism to this disease and enteric fever, however much we, in common with many of the highest authorities in England, India, and Germany might differ from him, we should never have characterised his views as agnostic; it was this general incredulity that we attacked, and which we naturally supposed was shared by Mr. Lawson when he came forward as the champion of his absent friend, without stating that he differed from him as regards the entire class of contagious diseases, properly so-called. We really cannot go into the question of the negative evidence of the Southampton and New Orleans outbreaks, beyond reminding Mr. Lawson again, that on page 101 of the United States report he will find good reason to doubt the nature of the epidemic. At another time and place we may continue the discussion, but must decline to return to it at present.

THE WRITER OF THE ARTICLES.]

WATER ANALYSIS.

[To the Editor of the Medical Times.]

SIR,—Your note in the *Medical Times*, February 23rd, p. 252, states that in the discussion on water analysis at the Society of Medical Officers of Health, it was the general feeling of the meeting that "the analysis should rather be deemed subsidiary to, and confirmative of, microscopical, physiological, and other evidence." Certainly neither the paper itself nor the observations of those qualified to pass an opinion upon the subject will bear this interpretation, and the statement quoted is, so far as my impressions may be trusted, not correct. The gist of my own remarks was, that *no one method of investigation should be exalted at the expense of another*—that very bad and very good waters alike presented little difficulty, but some on the border line required not alone chemical but biological methods; that the system proposed at the Society of Analysts, some time back, of giving a definite value to the appearance, odour, microscopical characters, chlorine, nitrates, &c., in a water was useful, and that my own practice was never to make a report upon a water without previously cultivating it in sterilised broths or syrups. These remarks were not dissented from, but it is obvious they were not intended to depreciate the value of chemical analysis as applied to water.

I am, Sir, &c.,

A. WYNTER BLYTH.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, February 21, 1884:—

Bailey, Wm. Henry, Colney-heath Rectory, St. Alban's, Herts.
Becher, Geo. Jno. Dashwood, Endsleigh-st., Tavistock-square, W.C.
Brooks, Samuel Jno., Tollington-park, N.
Cooper, Jno. Wilford, Hungerton, Grantham.
Eliot, Ernest Fred., Aston Vicarage, Birmingham.
Gwynne, Jno. Hickling, The Poplars, Cannock, Staffordshire.
Haydon, Hillyard Wm., Cholmeley Park-house, Highgate, N.

LONDON SANITARY PROTECTION ASSOCIATION.—The third annual general meeting was held on February 23rd at 1, Adam Street, Adelphi. The Chairman (Mr. Hugh Leonard) read the report of Council, and moved its adoption. The report stated that the membership on December 31st, 1883, had reached 723, including Eton College and all the boarding-houses there, the governing body being reckoned as one member only. During the year the engineers had inspected 404 houses for the first time, the majority of them being in London, but some at great distances, such as the neighbourhoods of Norwich, Lynn, Bury St. Edmunds, Sherborne, Wimborne, &c. This made a total of 927 houses inspected and reported upon by the engineers of the Association in the three years of its existence, most of them three or four times. Similar associations were springing up rapidly in the provinces, to all of which the officers of the London Association gave all the assistance in their power. There were already nine such societies in existence, and three more would be founded very shortly. It was a matter of deep regret to the Council that the aid of the Association had not been more freely sought for in connection with the improvement of the dwellings of the poor, but they hoped that if the Mansion House Council on that subject, and the numerous Sanitary Aid Committees now being formed, placed themselves in communication with that Association, they might work in harmony, and much good might result.—Mr. Timothy Holmes, M.A., F.R.C.S., the honorary treasurer, in presenting his balance-sheet, said that there was a net balance of 150*l.* to be carried forward. This had encouraged the Council to engage a fourth engineer, in the person of Mr. Alexander Kyd.—Several gentlemen having addressed the meeting, Dr. Whitelegge, the executive officer of the Mansion House Council on the Dwellings of the Poor, asked how far that Association was willing to assist the Mansion House Council in the work they had undertaken.—Dr. Bristowe, F.R.S., a member of Council, said that as a medical officer of health he deprecated the idea of the Association setting itself in opposition to any body of men such as the parish authorities, or mixing itself up in any contentious business which was likely to lead to litigation; and Mr. Holmes, the treasurer, having spoken to the same effect, the chairman replied that the matter would be taken into the careful consideration of the Standing Committee of the Council. The chairman then moved the adoption of the report which was seconded by Dr. Bristowe, and carried unanimously. The formal business of the election of president and council for 1884 was then proceeded with; and the whole of the outgoing council were declared to be re-elected, with the addition to their number of General Lord Chelmsford, G.C.B. His Grace the Duke of Argyll was elected as president. A vote of thanks to the Council terminated the proceedings.

SANITARY ASSURANCE ASSOCIATION.—The third annual meeting of this association was held at 5, Argyll-place, Regent-street, on Monday last, Dr. George Danford Thomas in the Chair. Mr. Joseph Hadley, the secretary, read the annual report and balance-sheet for the year 1883, in which the council explain that after the experience of three years, they have made such alterations in the details of their work as have enabled them to reduce the charges, both for houses in London and in the country. The property inspected during the year has varied in rateable value from 10*l.* to 1,000*l.*, and in every case of property placed on the assurance register for the first time, the sanitary arrangements have been found to be more or less defective; but the annual inspections have shown that houses certified by the association have remained in perfect sanitary condition. Dr. Norman Chevers, C.I.E., and Captain Douglas Galton, C.B., F.R.S., had given free public lectures for the association during the year. A special committee had been appointed to consider whether a measure should not be introduced into Parliament, for "compelling builders of all new dwellings to obtain a certificate from some authority, or qualified person, as to the sanitary condition of such dwellings before it shall be lawful for them to be inhabited." Dr. James Stevenson, Medical Officer of Health for Paddington, has succeeded Professor Corfield, as medical officer to the association. The association has become self-supporting, and the council anticipate that in future its progress will be greater than it has been in the past. After allowing for all liabilities, the accounts show a balance in favour of the association. The Chairman, in proposing the adoption of the report, said that after carrying on the association for three years, the council were so satisfied with the result, especially with regard to the granting of sanitary certificates, that they had carefully revised the detail of their work, and they entered on their fourth year with every confidence in the continued prosperity of the association. Mr. Barrington Kennett, Asylums Board,

seconded the adoption of the report, which was unanimously agreed to. Mr. George Aitchison, A.R.A., F.R.I.B.A., and Professor F. de Chaumont, M.D., F.R.S., were re-elected members of the executive council, and a vote of thanks to the Chairman concluded the business.

Bequests to Hospitals.—The late Mr. Alexander Black, of Hyde Park-gardens, has left 50*l.* each to the Royal Infirmary, Aberdeen; the Lunatic Asylum, Aberdeen; and the Hospital for Incurables, Aberdeen; and 30*l.* to the Aberdeen Dispensary. The late Rev. Edward Richard Benyon, of Culford Hall, near Bury St. Edmunds, has bequeathed 500*l.* to the Suffolk General Hospital. The late Mr. Henry Parker, the Centre Row, Covent-garden Market, has bequeathed 1,000*l.* each to Charing-cross Hospital, King's College Hospital, Brompton Hospital for Consumption and Diseases of the Chest, and the Brompton Hospital for Cancer, and the Covent-garden Lifeboat Fund; 1,000*l.* to the rector and churchwardens of the parish of St. Paul's, Covent-garden, the dividends to be distributed annually at Christmas in sums of not less than 5*s.* and not more than 1*l.* among the thoroughly deserving poor of the said parish; and considerable legacies to his niece, nephews, executors, old friends, and old servants. The residue of his property he gives to his old and faithful servant, Thomas Day; and the late Mr. Charles Beville Dryden, of Lincoln's Inn-fields, has bequeathed 900*l.* Consols to King's College Hospital.

A New Lunatic Asylum for Middlesex.—A special committee, appointed by the Middlesex magistrates to report on the accommodation for pauper lunatics, has recommended that an asylum be provided within the metropolitan area, upon a site of 30 acres or thereabouts, specially designed for the treatment of acute cases, such being intended for the accommodation of from eight hundred to one thousand patients. Mr. Adams moved the adoption of the report, and said it would be for the interest of the ratepayers that another asylum should be provided within the metropolitan area, and, although the land might cost a little more, it would be cheaper in the end, as they would not have to provide gas or water works, brewery or bakery. After some discussion it was agreed to defer the further consideration of the subject.

Army Medical Department.—Brigade-Surg. Eugene Francis O'Leary, M.D., retired, has been granted the honorary rank of Deputy-Surgeon-General. The undermentioned Surgeons on probation to be Surgeons:—Oswald George Dyx Bradshaw, Michael Kelly, M.D., Horace Henderson Pinching, Robert James Geddes, M.B., William Kelly, M.D., David Valentine O'Connell, M.D., Anthony Dodd, George Wilson, M.B., James More Reid, Thomas Bassell Winter, Frederick Samuel Heuston, Robert James Anderson Durant, George Frederick Gubbins, James Percival Myles, Robert Lesly, M.B., Henry Priestley Birch, Monckton O'Dell Braddell, M.B., James John Conway Donnet, Henry Maxwell Sloggett, Clement Sumner Robinson.

National Hospital for the Paralysed and Epileptic.—The Lord Mayor, supported by Lord Shaftesbury, K.G., Lord Thurlow, Dr. Vaughan (Master of the Temple), Rev. O. Dykes, D.D., Cardinal Manning, Hon. Geo. Cubitt, M.P., Mr. Samuel Morley, M.P., Sir H. Giffard, Q.C., M.P., Mr. John Marshall, F.R.S., Sir Andrew Clark, Bart., M.D., Sir Risdon Bennett, M.D., and others, is to preside at a meeting in the Mansion House on Friday, the 21st March, in aid of completing the new building of the National Hospital for the Paralysed and Epileptic.

Salicylic Acid as a Food Preservative.—A short time back we gave the substance of the report of the French Hygienic Committee on the use of salicylic acid as a food preservative. We now learn that the French Minister of Commerce has just issued a circular to the Prefect of Police on the subject. He has submitted the question once more to the Consulative Hygienic Committee, and the committee has recommended him to keep up the prohibition of salicylic acid for such purposes, as being a dangerous ingredient for daily consumption, especially if the liver or kidneys be effected. The custom-house officers have already received instructions to report any articles of food containing the obnoxious acid that pass through their hands, and other officials are to receive instructions to the same end as regards substances of home manufacture.

Greenock Infirmary.—The annual meeting of the directors and subscribers of the Greenock Infirmary was held on Thursday week. The report showed that the total admissions in 1883 were 1,325, showing an increase of 19 over the previous year. The fever-house admissions were 289, or 76 fewer. The total number treated to a termination were 1,355, and the mortality was 110, or 8·2 per cent., as against 9·3 per cent. in 1882. The financial sheet showed that the debt of 2,310*l.* existing at the beginning of 1883 had been wiped off by a public subscription, which amounted to 2,876*l.* The ordinary income for 1883 was 4,598*l.*, being a slight decrease compared with the previous twelve months. The ordinary expenditure for 1883 was 6,110*l.* The report was unanimously adopted.

Glasgow Hospital for Sick Children.—The first annual meeting of subscribers to the Glasgow Hospital for Sick Children was held on Wednesday, the 20th ultimo, the report for the year stated that from January 8th, to November 30th, 260 patients had been admitted, of whom 103 had been cured, sixteen had died, 89 had been discharged, and 52 remained in the house. Of the patients, 230 belonged to the city and suburbs. Donations amounting to 4,849*l.* 19*s.*, and legacies amounting to 490*l.* had been received, 12,510*l.* 0*s.* 2*d.* had been spent in erecting and equipping the hospital, and in purchasing the site, and there was a balance left in hand of 312*l.* 8*s.* 8½*d.* The Chairman in moving the adoption of the report, said it laid before the public of Glasgow what he thought was almost unparalleled—namely, that that beautiful little hospital, equipped with all modern appliances, and in every way as such an institution should be, was now, after having been carried on successfully for a year, about to be handed over to the citizens of Glasgow free of debt. Professor Leishman seconded the adoption of the report, which was unanimously approved. The office-bearers were afterwards elected.

Stroud General Hospital.—From the annual report which has just come into our hands, we gather that matters at this institution are tolerably satisfactory. During 1883, the in-patients numbered 801, the out-patients 2,475, whilst 122 were treated at their own homes. The total expenditure for the year was 1,645*l.* 9*s.* 10*d.*, or 20*l.* in excess of last year, whilst there has been a falling-off in the regular subscriptions. But the Committee have, nevertheless, been able to invest the lagacies received, which amounted to 230*l.* The hospital has sustained a great loss in the death of President, Mr. Capel, who had been connected with the management for thirty years.

The Sanitary History of Berkshire for the Year 1882.—The sanitary history of the county of Berkshire, for the year 1882, compiled by Dr. W. T. G. Woodforde, medical officer of health for the combined districts of Berks, does not contain any information of exceptional interest. Before proceeding to analyse the vital statistics of this county, it may be as well to remark that it is divided into twelve districts, Newbury (two), Hungerford, Abingdon (two), Wallingford (two), Bradfield, Cookham (two), Easthampstead, and Windsor (rural). The mean birth-rate for the year under notice was 31·0, and the mean death-rate 16·0 per 1,000; the latter, though higher than that for the previous year, being about equal to the average of the past five years. It is somewhat singular to note that the death-rate varies considerably in the different districts, ranging from 13·8 in the Bradfield Rural Sanitary District, to 24·9 per 1,000 in the Wallingford Urban Sanitary District. This latter rate, as might have been expected, enlisted the particular attention of Dr. Woodforde, and several sanitary improvements were at once undertaken; four samples of drinking water taken from the public pumps, were all found on analysis to be polluted, three of them to a large extent, and in calling the attention of the authority to this circumstance, Dr. Woodforde pointed out that while no infectious cases had been reported, and there had been in that district an admitted absence of zymotic mortality, this unusually high death-rate was so far an indication of a poor condition of

the public health. The zymotic death-rate in this district was, in fact, only ·4 per 1,000, and it ranged upwards to 4·2 per 1,000, in the Newbury Urban Sanitary District; the mean rate, however, for the whole of the county during the year 1882, was 2·1 per 1,000.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—The annual general court of the Governors of the Royal Hospital for Children and Women, in the Waterloo Road, was held on Tuesday, the Lord Mayor presiding. The report of the committee stated that the past year had been one of much importance to the hospital, several alterations which were urgently required, having been carried out. During the year there had been 465 in-patients, 6,874 out-patients, while the attendance of patients numbered 27,849. Both the in-patient and out-patient department had worked satisfactorily, and 220 sick children had been visited at home. The committee drew attention to the fact that there was a deficit of more than 400*l.* at the close of the year, and appealed most earnestly for new annual subscriptions.

CAMBRIDGE UNIVERSITY.—The following have been elected members of the Board of Electors to to the undermentioned professorships, until February 20th, 1892:—Chemistry, Professor Dewar; Anatomy, Dr. Paget; Botany, Professor Michael Foster; Zoology and Comparative Anatomy, Professor Michael Foster; Downing Professor of Medicine, Dr. T. Lander Brunton; Physiology, Mr. J. N. Langley; Pathology, Dr. Latham; Surgery, Mr. Timothy Holmes; Dr. Hans Gadow, Strickland Curator, has been approved as teacher of Comparative Anatomy; Mr. Laurence Humphry, M.A., M.B., Trinity, as teacher of Pathological Anatomy; and Mr. E. H. Neville, Sidney Sussex, as a teacher of Practical Chemistry.

APPOINTMENTS.

BERRESFORD, R., L.S.A.—Junior Assistant House Surgeon to the Public Hospital and Dispensary, Sheffield, *vice* H. Lockwood, M.R.C.S., L.S.A., appointed Assistant House Surgeon.

BROOKS, W. T., M.B.—Physician to the Radcliffe Infirmary, Oxford.

CAIGER, F. F., M.B., B.S., M.R.C.S., L.R.C.P.—House Surgeon to St. Thomas's Hospital.

DINGLEY, E. A., M.D., M.R.C.S.—House Physician to the Wolverhampton General Hospital, *vice* Dr. Collier resigned.

GIBBS, ROBERT, M.R.C.S. Eng., L.S.A.—Medical Officer to the Teignmouth District, Newton Abbot Union.

GREEN, C. D., M.R.C.S., L.R.C.P.—House Physician to St. Thomas's Hospital.

GREEN, E. C., M.R.C.S., L.S.A., L.R.C.P.—House Surgeon to the Derbyshire General Infirmary.

GRINDON, FRANCIS J., M.R.C.S. Eng., L.S.A.—Medical Officer to the Sixth District, Newport Pagnell Union.

HULL, WALTER, M.B., M.R.C.S., L.R.C.P.—House Physician to St. Thomas's Hospital.

JOHNSTON, G. D., M.R.C.S., L.R.C.P.—House Surgeon to St. Thomas's Hospital.

JONES, W. WANSBROUGH, M.A., M.B., M.R.C.S.—Resident Accoucheur to St. Thomas's Hospital.

MADDISON, W. T., M.B.—Assistant Medical Officer to the Darenth Asylum for Imbecile Children.

MAGUIRE, R., M.D., M.R.C.P.—Demonstrator and Assistant Lecturer on Pathology, in the Owens College, Victoria University.

MARSH, JOHN H., L.R.C.S. Edin., L.R.C.P. Edin.—Medical Officer to the Hulton District, Bolton Union.

MARSH, O. E. B., L.R.C.P., M.R.C.S., L.M.—Honorary Surgeon to the Newport (Monmouth) Infirmary, *vice* B. Davies, M.D., resigned.

MCNEILL, R., M.D.—Medical Officer to the Gesto Hospital, Colonsay.

ORFORD, JOHN, M.R.C.S., L.R.C.P.—Reappointed House Physician, Non-resident, to St. Thomas's Hospital.

POPE, HENRY B., M.B., B.Ch. Dublin.—Medical Officer to the Eardisley District, Kington Union.

ROBINSON, H. B., M.R.C.S., L.R.C.P.—Clinical Assistant in the Special Department for Diseases of the Skin to St. Thomas's Hospital.

RYGATE, DAVID J., L.R.C.P. Lond., M.R.C.S. Eng., L.S.A.—Medical Officer to the Second District, Cambridge Union.

SANKEY, H. R. O., M.B.—Superintendent of the Warwick County Lunatic Asylum, *vice* the late Dr. Parsey.

SHEPPARD, W. J., M.B., M.S., M.R.C.S., L.R.C.P.—Assistant House Surgeon to St. Thomas's Hospital.

TOMSON, W. B., M.B., M.R.C.S., L.R.C.P.—Assistant House Physician to St. Thomas's Hospital.

TURNELL, ARTHUR P., M.R.C.S. Eng., L.S.A.—Medical Officer to the Fourth District, Cambridge Union.

VOIGHT, J. C., M.B., C.M.—Senior Resident Medical Officer to the Infirmary, Bury, Lancashire.

VACANCIES.

BIRKENHEAD BOROUGH HOSPITAL AND DISPENSARY.—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Candidates must be doubly qualified and registered. Applications, with testimonials, stating age, to be sent to the Chairman of the Weekly Board, on or before March 3rd.

DRIFFIELD UNION, DRIFFIELD DISTRICT, AND THE WORKHOUSE.—Medical Officer. Area 14,460 acres. Population 7,017. Salary £56 per annum.

GENERAL HOSPITAL FOR SICK CHILDREN, PENDLEBURY, MANCHESTER.—Junior Resident Medical Officer. Salary £80 per annum, with board and lodging. Candidates must be doubly qualified, and on the Medical Register. Applications, stating age, and accompanied by testimonials (not original), to be sent to the Chairman of the Medical Board, on or before March 5th.

LEAMINGTON AMALGAMATED FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Resident Medical Officer. (*For particulars see Advertisement.*)

MARTLEY UNION, KNIGHTWICK DISTRICT.—Area 5,852 acres. Population 1,376. Salary £55 per annum.

MEMORIAL HOSPITAL, JARROW-ON-TYNE.—Resident Surgeon. Salary £150 per annum, with board in the Hospital. Candidates must be fully qualified, not under 25 years of age, and must engage to hold the appointment for three years. Applications with copies of testimonials to be sent to the Committee of Management on or before March 5th.

RUNCORN UNION.—Medical Officer. (*For particulars see Advertisement.*)

THE HOSPITAL FOR WOMEN, SOHO SQUARE, W.—Administrator of Anæsthetics. (*For particulars see Advertisement.*)

TOXTETH PARK TOWNSHIP.—Medical Officer. Salary £110 per annum.

WEST KENT GENERAL HOSPITAL, MAIDSTONE.—House Surgeon. Salary £120 per annum, increasing £10 per annum, to £150, with furnished apartments, coals, gas, and attendance. Candidates must be registered under the Medical Act, and unmarried. Applications and testimonials, accompanied by a certificate of registration, to be sent to the Secretary on or before March 6th.

WOLSTANTON AND BURSLEM UNION, TUNSTALL DISTRICT.—Medical Officer. Area 1,966 acres. Population 18,017. Salary £50 per annum.

WONFORD HOUSE HOSPITAL FOR THE INSANE, NEAR EXETER.—Resident Medical Superintendent. Salary £500 a year, with furnished residence, board, washing, and attendance. Candidates must be registered both in Medicine and Surgery, and not less than 30 years of age. Applications, stating age, experience in the treatment of the insane, &c., whether married or single, with testimonials of recent date, to be addressed to the President, Committee of Management, Wonford House, Exeter, endorsed M.S., on or before March 11.

DEATHS.

FERNIE, ANDREW, M.D., at Barnstaple, Devon, on February 22nd, aged 51.

HICKINBOTHAM, JAMES, M.D., at 26, Broad Street, Birmingham, on February 22nd, aged 41.

MAC DONOGH, PATRICK, L.R.C.P., at New Zealand, on January 1st, aged 29.

WOOD, ALEX., M.D., F.R.C.P., at Strathearn Place, Edinburgh, on February 26th.

NOTES, QUERIES, AND REPLIES.

THE ROGERS TESTIMONIAL.

The promoters, of the expression of opinion, of Dr. Joseph Rogers public work, during upwards of thirty years, desire to inform the profession, and the public, that the Subscription List will remain open until the end of March.

The following is the thirteenth list of subscriptions:—Albert Southey, Esq., Colnbrook, £1 1*s.*; Dr. E. S. Willett, Isleworth, £1 1*s.*; Messrs. Pinching, Gravesend, 10*s.* 6*d.*; H. T. Wood, Esq., Calstock, Devon, 5*s.*; Dr. T. Morgan, Montgomery, 5*s.*

THE MARRIAGE OF COUSINS.

TO THE EDITOR OF THE MEDICAL TIMES.

SIR,—Can you inform me through the medium of your journal, if it is the general opinion of the medical profession that the marriage of first cousins is unadvisable, for the reason that the offspring of such unions are frequently mentally, or otherwise, afflicted? In a case in point, two cousins desire to marry, their respective fathers were *twin* brothers, and both died prematurely of consumption.

I am, Sir, Yours, &c.
J. B. W.

Constant Reader.—We have published all the pass-lists that have been sent to us. The Edinburgh list appeared in the *Medical Times* of February 16th.

W. Darley-Hartley, East London.—We regret that there is no vacancy in our Exchange List.

Dr. Althaus.—Letter unavoidably held over till next number.

COMMUNICATIONS RECEIVED—

Mr. J. HUTCHINSON, F.R.S., London; Dr. ALTHAUS, London; Dr. NORRIS WOLFENDEN, London; Dr. CURNOW, London; Mr. A. WYNTER BLYTH, London; Dr. WM. EWART, London; THE SECRETARY, APOTHECARIES' SOCIETY, London; Dr. C. A. TOD, St. Louis, U.S.A.; Mr. COLE, Warwick; Mr. W. TYRRELL, Malvern; THE HON. APPOINTMENTS FOR THE WEEK.

March 1. *Saturday* (*this day*).

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Royal Institution, 3 p.m.—Capt. Abney, "Photographic Action."

Royal Medical and Chirurgical Society, 8 p.m.—Annual Meeting for Election of Officers, &c. President's Address.

3. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopedic, 2 p.m.

Medical Society of London.—General Meeting at 8 p.m. Ordinary Meeting at 8.30 p.m. Surgeon-General Hunter will read a Paper "On the late Epidemic of Cholera in Egypt."

Odontological Society, 8 p.m.—Meeting, at 40, Leicester Square. Casual Communications by Messrs. E. L. Williams, W. Hern, F. N. Pedley, G. W. Field, A. S. Underwood, &c. Communications from Messrs. Dunn, of Florence, and F. R. Lloyd, of Agra, India, will be read.

Royal College of Surgeons of England, 4 p.m.—Prof. W. H. Flower, LL.D., F.R.S., F.R.C.S., will deliver his Fourth Lecture "On the Principal Types of the Human Species."

Royal Institution.—Prof. A. Geikie, "Scenery of the British Isles," at 3 p.m. General Monthly Meeting at 5 p.m.

4. *Tuesday.*

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Royal Institution, 3 p.m.—Prof. Gamgee, "Animal Heat."

Pathological Society of London, 8·30 p.m. — Mr. Barwell, "Neoplasm affecting the Knee-joint;" Mr. Lane, "Fracture of Cartilage of First Rib;" Dr. Hale White, "Insular Sclerosis;" Dr. Norman Moore, "Interstitial Disease of Ovary;" Mr. Bowlby, "Symmetrical Gangrene;" Dr. West, "Fibrotic Disease of Heart," "Stomach from Case of Carbolic Acid Poisoning," (card); Dr. Sharkey, "Œsophagus, Stomach, and Intestine, from Case of Carbolic Acid Poisoning," (card), "Lodgement of Fish Bone in Larynx," (card); Mr. Clutton, "Sarcoma of Tonsil," (Living Specimen), "Nasal Calculus," (card); "Myeloid Sarcoma of Head of Tibia," (card); Mr. Roger Williams, "Photograph of Congenital Absence of Femora;" Mr. Makins, "Obstruction of the Trachea in a Child, from Pressure by Bronchial Glands," (card); Mr. Golding Bird, "Micrococci from Infective Osteo-Myelitis," (card) Mr. Lockwood, "Right Aortic Arch," (card); Mr. Turner, "Intussusception with Fatty Tumour of Intestine," (card), "Tuberculosis after Scarlatina and Caseous Glands," (card); Mr. J. Hutchinson, jun., "Heart with Left Superior Vena Cava," (card), "Ankylosis of Cervical Vertebræ," (card).

5. *Wednesday.*

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Obstetrical Society, 8 p.m.—The following Papers will be read:—Dr. John Williams, "On the Corroding Ulcer of the Os Uteri;" Mr. Alban Doran, "On the Relation of Prolapse of the Vagina to Hernia," illustrated by two pedigrees. Specimens will be shown by Dr. Horrocks, and others.

Royal College of Surgeons of England, 4 p.m.—Prof. W. H. Flower, LL.D., F.R.S., F.R.C.S., will deliver his Fifth Lecture "On the Principal Types of the Human Species."

6. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Royal Institution, 3 p.m. — Prof. Tyndall, "The Older Electricity."

7. *Friday.*

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Royal College of Surgeons of England, 4 p.m.—Prof. W. H. Flower, LL.D., F.R.S., F.R.C.S., will deliver his Sixth Lecture "On the Principal Types of the Human Species."

Royal Institution, 8 p.m. — Mr. C. V. Boys, "Bicycles and Tricycles.

West London Medico-Chirurgical Society, 8 p.m.—The following Papers will be read:—Mr. Hendley, in conjunction with Mr. Benham, "A case of Poisoning by Ammoniate and Red Oxide of Mercury;' Mr. Howard Marsh, "Three cases of Osteotomy with interesting Complications;" Dr. Thudichum, "Two fatal cases of Peritonitis simulating Poisoning," and "Several cases of Ammonuria and of Exostosis in the Nasal Cavity, with Operation and Treatment," (he will also exhibit microscopic specimens of Microzymes); Mr. Bruce Clarke, "A case of Radical Cure of Hernia."

REMARKS UPON THE TREATMENT OF TYPHOID FEVER BY THE COLD BATH.

By SAMUEL WEST, M.D.,[1]

Physician to the Chest Hospital, Victoria Park; Assistant Physician to the Royal Free Hospital; Medical Registrar and Medical Tutor at St. Bartholomew's Hospital.

THE points to which I desire to direct attention are chiefly two:—first, I wish to speak briefly of the doctrine of fever, upon which this method of treatment is based; and, secondly, to refer to the statistics which have been published, and to consider the value of the conclusions which have been drawn from them.

Liebermeister commences his pamphlet[2] upon this subject with the following paragraph:—"The longer I am engaged in the careful study of fever, the more confirmed I become in my conviction that the manifold phenomena, the sum of which constitutes the complex of symptoms of fever, are in chief part only the results of one of these phenomena, viz., the increase of body temperature. It is the increase of body temperature which, according to my conception, is not only the pathognomonic symptom of fever, but also the proximate and sufficient cause of most of the other symptoms peculiar to fever, or characteristic of it; and, finally, it is also the increase of body temperature, which in the highest degree produces the danger of fever." In other words, the temperature is practically the cause of the symptoms of fever, and of the dangers which arise in it. That I am not straining Liebermeister's meaning is quite clear from numerous other passages in the same pamphlet.

It would be quite beyond the field of this discussion to criticise this statement with reference to fever generally; but we may with advantage consider its applicability to typhoid fever only.

Clinical observation is, I think, quite opposed to the acceptance of this proposition, as it stands, in the case of typhoid fever. It is certainly not our experience in this country that the dangers of typhoid fever vary in direct proportion to the height of the temperature. Numerous cases with high temperature recover, and many with low temperature die. Diarrhœa, exhaustion, hæmorrhage, perforation, and peritonitis, each has its own victims, and produces its own dangers quite irrespective of the temperature, although it has been asserted that a high temperature increases the risks of these complications, and it may be so. But the assertion has to be proved, and must not be assumed.

Liebermeister's statement, therefore, as it stands is incorrect, without so many reservations and conditions that it becomes practically of little value when applied to any individual case. I need hardly refer to other diseases, such as phthisis, or suppuration fever, in which

the temperature is high for long periods together, and in which no symptoms arise which call for the same active treatment as is demanded by the advocate of cold-bathing, with similar temperatures, in typhoid fever.

I would not, of course, deny that high temperature may in itself be a source of danger, but such cases belong to the general group of hyperpyrexiæ, a state the pathology of which we do not comprehend, and which may arise under so many divers conditions, that it is difficult to find a factor common to them all. Even supposing that it were proved, and this it is not, that a temperature of 103° or 104° were in itself a danger to life, and that by cold-bathing the temperature could be permanently reduced to its normal height, knowing so little as we do of the exact way in which a cold bath acts upon the body, we should not be justified in assuming, without further proof, that the improvement was due simply to reduction of temperature.

The facts known about fever seem to indicate that we have in fever a complex of co-ordinate symptoms, each of which may vary within wide limits—and this is true even of that symptom of which we are specially speaking now, viz., temperature—and that each and every one of these symptoms is due probably to some common cause as yet undetermined.

We must give account, to obtain any satisfactory explanation of fever, of the increased heart's action, of the sensorial and gastric disturbances, of the chills, of the increase of chemical metabolism, and of the diminution of secretions, as well as of the rise in temperature, of which each of the other phenomena is, it appears, essentially independent. This, however, is not the time for a dissertation upon the general question of fever. I have said this much, only to show that the theory, which appears to be often assumed by the chief advocates of this method of treatment, is one which is in all probability insufficient, and that, therefore, the treatment based upon this theory, will be probably also found insufficient.

But it might be urged, if the results of the treatment are good, they become an argument in favour of the theory upon which the treatment is established. This is a specious, but very dangerous argument to use in medicine, and it is hardly necessary to point out the many fallacies which it embraces. As, however, the results to which reference is made are obtained from statistics, I am brought naturally to the consideration of the second point of my paper, viz., the applicability of statistics to the solution of this problem.

The fallacies to which all statistical conclusions are exposed, are chiefly three.

1. Inaccurate observation and grouping of facts.
2. Insufficient number of facts.
3. Insufficient elimination of, or allowance for, disturbing causes.

In the particular case with which we have to deal, we may assume the correctness of the observations, and turn to the consideration of the last two sources of error—insufficient data, and disturbing causes.

The problem to be dealt with is one of the highest complexity. If it were possible to get two sets of observations, in all respects similar, except in regard to the treatment by cold-bathing, the one having this method of treatment and the other not, the comparison would be just and the conclusions final, but these conditions are clearly impossible of fulfilment.

The unreliability of comparative statistics in typhoid fever is, I think, generally recognised, and the disturbing causes are so great that it is impossible to make sufficient allowance for them. It is impossible, except in the most general way, to compare the statistics of one epidemic with those of another, or, indeed, of the same epidemic in different countries, or even in different parts of the same country, still less of different epidemics in different places. This is true, even of the same epidemic in different parts of the same town. I have drawn out upon the following table the mortality statistics of the last 23 years at St. Bartholomew's Hospital. The figures demonstrate very clearly the points to which I am referring :—

TABLE I.

Statistics of Typhoid Fever at St. Bartholomew's Hospital.

Year.	No. of Case.	Deaths.	Percentage.
1860	29	2	7·6
1861	49	10	20·4
1862	63	5	7·94
1863	41	3	7·52
1864	37	7	18·9
1865	55	9	16·36
1866	57	9	15·8
1867	61	14	20·3
1868	61	15	24·36
1869	47	14	30·0
1870	61	9	14·75
1871	72	10	13·9
1872	53	6	11·7
1873	80	13	16·25
1874	87	11	12·64
1875	46	3	6·52
1876	59	11	18·64
1877	77	13	16·9
1878	167	20	12·0
1879	103	19	18·45
1880	91	21	23·08
1881	126	32	25·4
1882	146	16	10·96
TOTAL	1,668	272	16·96

The total number of cases is 1,668, with 272 deaths, giving a percentage of mortality of 16·96, which agrees closely with that given by Murchison. When we compare the mortality year by year, it is surprising to find how great the variations are, from 6·52 per cent. up to 30 per cent. In fact, there are hardly any two, and certainly no three, consecutive years in which the percentage mortality is even approximately the same. Even in consecutive periods of five years the mortality differs widely, 14·6, 13·88, 19·8, 12·33; and the difference over periods of ten years, though of course less than for short periods, is still considerable, 17·6, 14·28. The statistical tables of the Middlesex Hospital, brought forward by Dr. Coupland; those of Guy's, by Dr. Frederick Taylor; and those of the London, by Dr. Gilbart Smith, show similar wide variations, and demonstrate the extreme need for caution in the comparison of typhoid fever statistics.

TABLE II.

Percentage over Periods of Five Years.

Period.	No. of Cases.	Deaths.	Percentage.
1860–4	219	27	12·33
1865–9	281	61	21·7
1870–4	353	49	13·9
1875–9	452	66	14·6
1881–3	363	69	19·01

Percentage over Periods of Ten Years.

1860–9	500	88	17·6
1870–9	805	115	14·28

If any results could be comparable with one another, it might be thought to be those of the different physicians in the same hospital, during the same epidemic. These statistics are shown upon Table III. for the last three years at St. Bartholomew's Hospital.

Of the four physicians—whom I may designate by the letters A, B, C, and D—one, viz., A, practised the cold-bath treatment with activity; the other three, B, C, D, used, if I may so call it, the modified cold-water treatment, endeavouring to reduce the temperature by cold-sponging, wet-packs, light clothing, drugs, &c., and using only the cold or tepid bath when the temperature was persistently very high. I thought, by comparing the results of the one with those of the other three, I might discover some facts of interest. The results are shown upon the Table III., in which are put out the number of cases, with the number of deaths in each year, and the percentage reckoned.

We find that A had under his care 110 cases, with 18 deaths, giving a percentage of 16·36; but the percentage in different years varies very widely, and in 1882 is more than double that of either of the other years.

Taking the practices of B, C, and D together, we find that there were 255 cases under treatment, with 45 deaths, giving a percentage of 17·65 which is not very different from the percentage of A; but when we analyse the figures of the B, C, and D group, and compare them with one another, we find the same great variations and irregularity, to which I have already referred, as occurring in every statistical table published upon the subject.

TABLE III.

Statistics of the Four Physicians during the Years:

A.

Sex.	1881.		1882.		1883.		Grand Totals.	
	Total No.	Deaths.	Total No.	Deaths.	Total No.	Deaths.	Total No.	Deaths.
Male	22	7	25	4	26	3	73	14
Female ..	12	2	11	0	14	2	37	4
Total ..	34	9	36	4	40	5	110	18
Percentage ..	11·1		26·5		12·5		16·36	

B.

Male	17	3	24	2	16	4	57	9
Female ..	8	0	16	1	12	2	36	3
Total ..	25	3	40	3	28	6	93	12
Percentage ..	12·0		7·5		21·48		12·9	

C.

Male	13	8	27	2	16	5	56	15
Female ..	12	4	7	1	10	1	29	6
Total ..	25	12	34	3	26	6	85	21
Percentage ..	48·0		8·82		23·1		24·7	

D.

Sex.	1881.		1882.		1883.		Grand Totals.	
	Total No.	Deaths.	Total No.	Deaths.	Total No.	Deaths.	Total No.	Deaths.
Male	13	2	11	2	9	1	33	5
Female ..	13	3	21	3	10	1	44	7
Total ..	26	5	32	5	19	2	77	12
Percentage ..	19·2		15·62		10·53		15·6	

These tables thus only accentuate one of the chief difficulties which we have to meet in dealing with medical statistics, and show, I think, conclusively the complexity of the disturbing causes for which, if logical conclusions are to be drawn, we must make adequate allowance.

Such statistics as these latter are, of course, open to the objection, that the numbers are small; but they are not smaller than some which have been published, and which are supposed to justify certain conclusions.

But all who are familiar with the working of a hospital know how largely such results as these may vary, in consequence of accidental causes, quite irrespective of treatment, depending, as it is often said, upon good or bad luck—one ward having a run of severe and another of light cases. How greatly chance enters into such results, is illustrated by an authentic tradition of St. Bartholomew's Hospital, upon the authority of the late Dr. Jeaffreson, who, for the first five years after he entered upon charge of the wards in the hospital, never had a single death from fever, and that when there was no isolation fever-ward in the hospital, but all cases of fever alike were admitted into the general ward indiscriminately. A similar experience befell also the late Dr. Black, who, for a period of eighteen months, never lost a single fever case. Such facts as these are very extraordinary, though, of course, quite accidental, but their bearing upon the present subject of discussion is clear.

The same evidence of disturbing causes is seen when the results of the various advocates of the cold bath are compared with one another, the percentage varying from 3·1 to 13·2.

Now on referring to the general table which Dr. Coupland quoted, giving the results of foreign observation, two strange facts strike me. First, the high rate of mortality taken as the average upon treatment other than cold-bathing; and, secondly, the extremely low mortality with that treatment. Such a wide divergence is, I venture to think, suspicious. In the first place, the average mortality assumed is excessive; a percentage of 30, 27, 26, 24 represents a mortality which is most unusual, and can be explained only on the assumption that either the numbers taken are too small, or that other diseases of a severe kind are included, for it is far in excess of our average in this country, which is about 16 to 18. Out of the 23 years at the London Fever Hospital (1848–70), from which Murchison draws his statistics, on only four occasions did the percentage exceed twenty, viz., 20·55, 26·97, 27·83, and 28·4. The possibility of error is openly acknowledged even by Liebermeister in the early statistics which he gives, where the mortality is stated to be 27·3.

Another striking fact, viz., the lowness of the percentage on cold-bath treatment, suggests the opposite possibility, viz., the inclusion among typhoid fever cases of a large number of mild or even doubtful cases, many of

which we classify in this country under an entirely different heading, such as ephemera febricula, &c., and which would seem to correspond with Jürgensen's "typhus levissimus." With reference to these light or mild cases, Liebermeister himself puts the percentage mortality of cases not treated antiseptically, in which the temperature did not rise above 101, at the remarkably low figure of 9·6. That the question of diagnosis assumes an important position in this consideration is also acknowledged in a very careful paper by Dr. Goltdammer, of Berlin, whose conclusions recommend themselves the more strongly because the subject is discussed in a more critical and less enthusiastic manner. This paper is a very important one: first, on account of the large number of cases with which it deals; and, secondly, on account of the caution which the author displays. The percentage given of the mortality of cases not treated by cold-bathing is 18·1, a number which closely approximates to our usual average in this country. By cold-bathing the mortality was reduced by five per cent., *i.e.*, to 13·2. But in criticising his own results, he makes several remarks which may throw light upon some of the other foreign statistics. He explains the comparative highness of his percentage upon the cold-water treatment, by stating that he has included all cases indiscriminately, and has not excluded those which came to the hospital in a hopeless state—this, I need not say, is a very suggestive remark. He adds further that, so far as he is aware, his results are not surpassed by those of any other hospital in Berlin. But even the difference of five per cent. in the mortality is small, and, as I have shown, comes well within the range of periodical variations. Dr. Cayley claims even a smaller percentage improvement than this, about 3 per cent.

I may refer in illustration to the statistical tables of heart-disease as a consequence of rheumatic fever given by various authors. One would have thought that, if any disease did admit of tolerably accurate diagnosis and classification, that disease would be rheumatic fever and its cardiac sequelæ, and yet the percentages differ so extraordinarily as to defy explanation. They range from so low a figure as 3 per cent. up to 50, 60, or even higher.

The only possible way of eliminating the fallacy of disturbing causes in statistics is by dealing with very large numbers, and even when the numbers are large the difficulties in excluding cases which do not really belong to the class become almost insuperable. Indeed I do not see how it is possible in the case of typhoid fever, to obtain sufficient data of the right kind. For these reasons I venture to think that the statistical method is not applicable to the solution of the problem we have before us.

By what means can this question then be solved? Believing, as I do, that it must be answered by individual experience, and not by statistics, I have thought I could best contribute to the discussion by eliciting the opinion of the physicians at St. Bartholomew's Hospital, who responded most readily to my request, and have given me their opinions in writing to communicate to this Society.

Dr. Andrew writes thus:—"I should not use the bath in any ordinary case of typhoid fever in which the temperature did not rise above 105°. It is impossible for me, in reasonable compass, to lay down the considerations which guide me in such cases. The duration of the hyperpyrexia, as well as its height, the period of the fever, the special tendency to death in the particular patient, his age, and the characters of the epidemic at the time, would have to be all taken into account. There are also gentle means of reducing the temperature in fever, the early employment of which may prevent the necessity for the bath arising, *e.g.*, attention to the temperature of the sick room, diminishing the amount of bedclothes, and especially by the use of cradles preventing the bedclothes being in actual contact with the body. This last is a most efficient means of reducing temperature; and from observation of its effects I am convinced that in fever, unless its natural crisis be close at hand, it is often injurious to reduce your patient's temperature much below 102°. For the bath, even when necessary, is not without dangers of its own. Pulmonary symptoms not infrequently develop, or become more serious after its use. In short, I look upon the bath as necessary in hyperpyrexia, needless and often harmful in ordinary cases."

Dr. Church's opinion I will quote from an article published by him in the St. Bartholomew's Hospital Reports for 1881:—"Although I have made pretty frequent use of the cold bath, I do not feel sure of the propriety of using it as a routine instrument for typhoid, after the manner of Dr. Brand, of Stettin, Prof. Liebermeister, and others, as recommended by Dr. Cayley in his Croonian Lectures. The difficulty which applies to all statistics, of estimating the probability of the circumstances under which they were compiled being identical with those with which you yourself are dealing, applies with increased weight to the statistics of foreign observers, and I must confess that foreign statistics have but little weight with me. Dr. Cayley's own statistics are, however, very satisfactory. He claims to have reduced the mortality of the severe cases to the level of the average mortality of the disease at the London Fever Hospital. The mortality at St. Bartholomew's very closely corresponds with that of the London Fever Hospital, and has not become less during the few years in which cold baths have been more or less in use there. Dr. Alexander Collie, at the Homerton Fever Hospital, came to the conclusion that cold bathing had no effect on the mortality there; but the number of cases in which he used the bath is not sufficiently large for any reliable deduction to be drawn from them. Another point which renders it necessary to be careful in forming any opinion from a comparison of statistics taken from a limited period, is the remarkable fluctuation in the rate of mortality from typhoid in different years.

"To give every patient a cold bath as often as the temperature rises to 102°, appears to me a most unnecessary amount of fatigue, both to the patient and his attendants. I have no statistics on the subject, but I should say the mortality from typhoid in cases where the temperature does not reach above 102° is extremely small, and if to them be added all the cases of pyrexia, which may be classed as Professor Jürgensen's "typhus levissimus," I can conceive that very favourable statistics might be obtained for any form of treatment not directly hurtful.

"During the last four years, *i.e.*, up to 1881, I have used the cold bath on adults whenever the temperature has remained for 24 hours or so persistently at or about 104°, and have repeated the bath three times in the 24 hours, but not oftener. This utility of cold-bathing in cases of extremely high temperature is well illustrated by Case 1 (quoted in the paper). On the other hand, little or no benefit was obtained from its use in Case 8. Cold sponging, which is almost invariably grateful to the feelings of the patient, is constantly used, though it appears to me to have but a transient effect on the temperature. All my patients are kept very lightly covered with bedclothes."

This opinion, stated in 1881, the further experience of the last three years has only confirmed.

Dr. Gee writes thus:—"Thinking over the promise I made in answer to your request, I find that I have very little to say, and that the value of that little is still less. My febrifuge treatment is no more than to let the patient lie as lightly clad as possible. Sometimes, but seldom, if the fever rise very high,

they are sponged with luke-warm water once a-day, or oftener if need be.

"I have followed the question of cold-bathing in typhoid fever ever since its first introduction in Germany, and I have been waiting for better proof than I have yet found, that such treatment is beneficial, before I cared to subject my patients to what seemed to me to be a severe method of cure."

Dr. Southey states his opinions thus:—"Cold baths answer well as 'stirs,' are admirably suited to cases of enteric, which are early overwhelmed with typhus-like symptoms, and present a very ataxic condition, cases with much subsultus, delirium, and passive lung congestion. I dipped several patients into cold water, temperature of ward 55°–65°, but only in and out again twice or three times in the 24 hours. I continued this in some cases for two or three days. It loses effect, this cold dipping, after too frequent repetition, but is capital in procuring quiet sleep, when resorted to in suitable cases. Employed after the third week it was found too often succeeded by hæmorrhage from the bowels, to doubt its ill effects in this direction.

"Any bathing is good in the first two weeks, cold or tepid, but the baths are after a short time succeeded by an elevation of temperature, unless protracted so as to require warmth and stimulants. Indeed, when I used cold baths, longer than mere dips, I doubted their being so efficacious in lowering temperature as tepid baths taken at 95, and protracted for 15–25 minutes, or until the patient shivered. The tepid baths were not in a single case that I had followed by hæmorrhage, so far as I can recollect."

It is noteworthy that with so considerable an experience of the cold-water treatment, Dr. Southey's opinion should still be so cautious and so far from enthusiastic.

Dr. Duckworth has sent me the following communication, in which his opinion is stated:—"I have had experience of the cold-bath treatment of typhoid fever. For some time cases with hyperpyrexia were thus frequently treated by several of my colleagues, and by myself, at St. Bartholomew's. I think I may say that this practice has now become almost obsolete with us. Not that, as a therapeutic measure, it is absolutely discarded, but it is held in reserve for cases which appear to require it.

"Had I been present at the recent discussions, I should like to have remarked that in the treatment of any disease I regard it as always essential to make a distinction between treating the malady and treating the patient, and I wish this all-important point were oftener borne in mind than it is. Next, I make a clear distinction between what I may call ordinary cases of well-marked typhoid fever, and those in which hyperpyrexia occurs. I consider that a temperature of 105° indicates the beginning of hyperpyrexia. Below that I do not consider a case hyperpyretic, or as exciting any undue anxiety as to the ultimate issue of the disease. I am perfectly satisfied that it is quite unnecessary to employ the cold bath for cases which are not hyperpyretic. I never have any trouble with such cases, and find that the upward pyretic tendency can commonly be checked by what we term the air-bath—that is, by a cradle placed over the limbs, the bed-clothes being raised, and a current of air allowed to pass over the patient's body. This is very effectual in moderating undue thermic tendency. If this fails, I order cold sponging to the limbs, with or without the addition of a bag of ice to the head. Certainly, the great majority of cases, in my experience, need no more in this direction. If, however, the temperature shows persistent disposition to rise in spite of these measures, I employ five or ten grain doses of quinine, or instead, a few doses of salicylate of soda, always prefering the former however, and by this means commonly find the pyrexia under control. I am fully satisfied that for the great majority of cases no further measures are required or, I may add, justifiable. Hyperpyrexia, as I understand it, is not a common complication. When it does occur, I am prepared to use the bath with the ordinary precautions, and as often as may be necessary, and I have no fear of inducing internal congestion or hæmorrhage in such cases. To use it in the other class of cases, I should consider *nimia diligentia*. The cold-bath treatment is practically available for but few other than hospital cases. The process is a very troublesome and fatiguing one for the ward staff, even with the best modern arrangements for moving the patient. Nothing but its absolute necessity would justify such an addition to the labour and anxiety of the resident and nursing staff.

"I am quite sure that it is often practised when it is unnecessary, but I do not affirm that it is injurious in such cases. I think other frigorific measures short of it suffice for most cases. Cold-bathing I regard as a most valuable therapeutic agent in true hyperpyrexia, however induced. I reserve to myself the employment of it whenever I require it in practice, and relegate it to the same position as the lancet, the cupping glass, the use of calomel or alcohol, or, in short, any other potent and well-recognised agent for the treatment of disease."

The experience of St. Bartholomew's Hospital, therefore, is very clearly in favour only of the modified cold-water treatment, *e.g.*, of the use of bathing in cases where the temperature is persistently high, as an adjunct to other antipyretic methods; and here I may remark that the use of the cold bath in typhoid fever patients with a low temperature, say 102°, without harm accruing, proves no more than that the risks of constant bathing are not so great as have been anticipated, but does not prove that the chance of life is in any way increased by it.

Although I would speak with diffidence of my own personal experience, still, as I have been for some years much interested in this question, I may be allowed, without presumption, to say, that I agree entirely in the results which experience has arrived at at St. Bartholomew's Hospital, and I confess at once, that I cannot reconcile the enthusiastic statements of the advocates of cold-bathing with my own observations and experience.

It appears to me, that when the temperature does not rise above 102°, or probably 103°, the cold bath, if it does no harm, does at any rate no good, and is, therefore, I think, unnecessary. Of the cases with higher temperature, there are two classes in which antipyretic treatment is of great service:—first, that in which the temperature runs up to an unusual height, say 106° or higher, even though this level be maintained only for a short time; and, secondly, that in which the temperature, though never so high at any one time as in the preceding group, still preserves a constant high level, say of 104°, and in which the usual daily remissions are small or absent. But these are the very cases in which all writers seem to agree, that treatment by cold baths involves too much fatigue and excitement to be at all times applicable, and under these circumstances accessory measures must be adopted, such as cold sponging, wet-packing, light clothing, and antipyretic drugs, remedies which though not in all cases of equal efficacy with cold bathing, are, at any rate, many of them, free from its special disadvantages.

In conclusion, I would restate the points which I have endeavoured to establish in this paper:—

1. That the thorough cold-water treatment of typhoid fever is based upon what appears to be a one-sided view of the process of fever.

*

2. That the question is one which cannot be satisfactorily determined by statistics.

3. That a general opinion has gradually developed, which, whatever statistics may appear to prove, cannot be disregarded against the indiscriminate use of bathing, and in favour of its use in appropriate cases.

4. That, while not denying that in hyperpyretic cases cold-bathing is the most valuable of the known methods of treatment, in the less severe cases it stands only on the same level as many other antipyretic remedies; and

5. That the success of the treatment depends chiefly upon the clinical skill which recognises the proper circumstances for its use.

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA, ESPECIALLY THOSE PREVALENT IN BENGAL.

By NORMAN CHEVERS, C.I.E., M.D.,
President of the Epidemiological Society of London.

Diseased Conditions consequent upon Malarial Cachexia.

(*Continued from page* 179.)

Treatment of Elephantiasis.

When we can get a scrotal or limb case early, and duly combat the fever and the local inflammation, principally by quinine and by the application of iodine (iodised oil and iodine paint—Webb), and by rest, especially in the inflammatory stage, as well as by mechanical support and bandaging (Dalton), we can often effect so much good that I used to encourage my students by telling them that, when they were in attendance upon patients in independent circumstances, who would take care of themselves and obey instructions, extensive growth might always be checked, and that such cases might be dealt with hopefully.

When the disease occurs in Lower Bengal, I certainly have faith in the efficacy of quinine *in the earliest stage* of these growths, but my friend Dr. Francis Day, observed, as the the result of great experience of the Cochin disease, "Anti-periodics I have found of no utility except in their tonic action. I am so convinced, from experience, that large doses of quinine are only a waste of medicine, that I never employ them."

Fayrer shows that a complete change of climate, far inland to the native; to a temperate climate to the European, is a distinct indication. He observes that it has occasionally been observed in the rare cases in which elephantiasis affects Europeans, that, returning to Europe, they have, after a time, lost the disease, and almost, if not entirely, any hypertrophic changes that may have occurred. Webb gives the case of a native of Bengal, in whom the disease remained stationary during twenty years' service at Agra. On his return to Calcutta, he, in a few months, had repeated attacks of the fever, with swelling and inflammation of the scrotum, and, much against his will, had to go back to the Upper Provinces. Thus his disease treated him as my asthma did me on two occasions.

Dr. Day's Cochin experience fully confirms this observation. A native left that place, elephantiasis having been ineffectually treated. He went to sea, was absent eight years, and returned perfectly restored to health, all signs of effusion having quite disappeared. Shortly after this elephantiasis again attacked him. A person went forty miles inland, staying two years; the disease quite left him, and, though he returned to Cochin and resided there for a long time, it did not reappear. On the other hand, a child was sent away, above a hundred miles inland, but the disease did not leave her. Most growths are obstinate in growing children; Dr. Day enjoins a tonic treatment, in addition to the change of residence, for the eradication of the cachexia. When the mischief has gone far, as it too generally has when cases come to us, the tumour having attained a permanent weight of pounds, removal by the knife is alone effectual.

Dr. G. R. Ballingall[22] urges early removal by knife when the disease is progressing rapidly and is attended with recurring febrile attacks, to prevent impairment of the constitution.

All operators—Webb, Fayrer, Day, Ballingall, &c.—agree that, with the ablation of the growth, fever ceases. Day gives an exceptional case, which proves the rule—elephantiasis existing in another limb, fever recurred after an operation

Frequently, in Bengal, empirics declare that they can effect a cure without recourse to the knife. They remove a great deal of fluid, either by bandaging or by the application of the *gool*, but without the slightest benefit. Indeed, whatever condenses the tumour, hardening it by superinduced inflammation, and produces adhesion between the integument and the testes, as the *gool* treatment often does, embarasses the operator, imperils the testicles, renders the operation tedious, and places the patient in great danger of death by hæmorrhage.

I regret that, although the search at first seemed easy, I have not been able to discover the name of the surgeon who first dared, in these cases, to remove the whole integument of the genitals, trusting that nature would, as she does, cover the exposed parts in a few weeks with new integument, extended from pubes, thighs, and perineum, and supplemented by granulation. It will be recollected that, in operating upon the Chinaman Hoo Loo, at Guy's Hospital, in 1831, Mr. Key lost so much time in endeavouring to save the genitals and to dissect out flaps, which would either have sloughed away or reproduced the growth, that the patient died from hæmorrhage. Calcutta surgeons made flaps then, and for some years afterwards—at least up to 1842. Dr. Ballingall leaves flaps where, as frequently happens in the form of disease prevalent in Bombay, the prepuce is unaffected, and the skin at the sides, drawn down from the abdomen and thighs, appears healthy. This, he finds, facilitates healing, and in no case has inflammation reappeared in the flaps. I have never seen, in a multitude of Bengal cases, one in which healthy skin appeared to be available to form flaps. But, of late, Dr. Kenneth McLeod, of Calcutta, has employed a flap operation, successfully, doubtless in cases where there was more or less healthy skin available.

Mr. F. H. Brett, of Calcutta, was the first surgeon who succeeded, in 1837, in preserving the genitals in removing a tumour as large as Hoo Loo's. We sometimes hear of a wretched native, who, having been thrown down, is dragged along by the scrotum until the whole integument is torn away. The surgeon may have seen such a case, and may have noticed how well loss of this integument by infiltration of urine is repaired, or the flaps may have sloughed in some of his cases, when he must have observed that Nature did far better without them. Still, when we consider that, in many of these cases, the denuded cords are half a yard long, we cannot but accord honour to him who first performed this operation. A still higher meed of credit is due to my friend, Mr. Samuel Bowen Partridge, F.R.C.S., for his admirable adaption of Esmarch's bandage in the removal of these tumours.

I saw my friend Sir Joseph Fayrer remove a scrotal integument which, with its fluids, weighed rather more

[22] "Scrotal Tumours in Bombay." — *Bombay Med. and Phys. Trans.*, 1859, p. 1.

than the man did. The man weighed one hundred and eight pounds; the mass, with its fluids, two pounds more. I am not sure how large a tumour has been removed with perfect success. Mr. Partridge reported, in 1880,[23] that the wound was cicatrising after the removal of a mass which weighed 111 pounds, exclusive of serum (of which there were doubtless enormous accumulations in the tunicæ vaginales) and blood.

Dr. James Irving has recorded the particulars of a case[24] in which the excised mass weighed, without its fluids, 136 pounds. The testicles were not saved. Dr. Irving cites the case of a Jew, at Gibraltar, from whom Mr. Hugh Fraser removed a scrotal tumour, weighing 150 pounds. The penis and testes were preserved, and the man made a perfect recovery. This was probably the largest tumour ever removed with success. But larger scrotal growths have been removed unsuccessfully, or with uncertain result. Dr. Irving reported a second case in which he removed a tumour, weighing 152 pounds without its fluids (later it became customary to weigh the patient before operating). The man lived seventeen days, and did well until the fifth day. His death was caused by severe attacks of intermittent fever and diarrhœa. Mr. Irving cites Samuel Cooper for a case of uncertain issue, in which a scrotal tumour, weighing "about a hundred kilogrammes," or 224 pounds, was removed.

Of 193 cases of scrotal elephantiasis operated on in the Calcutta Medical College Hospital, 18·2 per cent. proved fatal.[25]

In his "Treatise on the Diseases most frequent in the West Indies," published in 1726, Richard Towne says, of Barbadoes, that "Amputation of the diseased leg has been performed many times, but has always failed of a cure, for the disease constantly takes possession of the remaining leg." They did not know quinine then.

Sir Joseph Fayrer has shown[26] that ligature of the femoral artery has been fairly tried in India, but with no permanent improvement: "The disease returned to its original dimensions when the patient resumed his usual mode of life."

The natives of Lower Bengal often suffer, in malarious fever, from a very troublesome congestion and swelling of the Schneiderian mucous membrane. In this *Nakra* they consider that they obtain relief by thrusting a prickly grass up the nostril, so as to cause bleeding.[27]

Malarious Influence in cases of Wounds, &c.—I much regret the loss of a note of the observation made by an English surgeon (I think Mr. James Arnott), to the effect that, in England, surgical fever is apt to assume the periodic character in patients from marshy districts. We have abundant evidence of this fact in Bengal. Again, Sir Joseph Fayrer gives, in his second Croonian Lecture, some most interesting observations by Mr. Eccles, a surgeon of the Stafford House Ambulances during the late Russo-Turkish campaign, on the effects of malarial fever on wounds. Sir Joseph's own experience confirms that of Mr. Eccles. I saw, in my colleague's wards, the cases of death from *Urethral Fever* and *Gangrene from Wasp Sting* to which he refers in the following quotation: "The mere passing of a catheter in a comparatively healthy man has been followed by paroxysms of fever and deposits of fibrine in the pulmonary artery, which have proved rapidly fatal. The slightest wounds have, in those more deeply affected" (by malarious cachexia), "been followed either by gangrene or by hæmorrhage — the abstraction of a tooth, by necrosis of the jaw; a pimple on the face, by gangrene of the cheek; or the sting of a wasp, by gangrene of a limb—all proving the low vitality and tendency to disintegration of the tissues n this diseased condition."

A few remarks upon *Urethral Fever*, depending upon paludal influence, as it occurs in India and in England, will be found in the *Medical Times and Gazette*, vol. ii., for 1883, p. 501.

Puerperal Fever.

It was remarked by Lind, in the last century, when Calcutta and the other Presidency towns were very unhealthy, that, in India, European women in general enjoyed a much better state of health than the men, but that child-bearing was, in his time, peculiarly fatal to them in Calcutta; on which account he considered that it would be advisable for them to retire to a more healthy situation at the approach of their delivery. In the absence of more explicit information regarding the prevailing causes of death, we may state the probability that *post-partum hæmorrhage* destroyed many who were the subjects of neglected malarial cachexia. This dangerous accident is still always so much to be dreaded in India that I never omitted to have a sheet-binder placed under the patient from the first, and to give a full dose of ergot as soon as I knew that the child was descending quickly. Clarke, writing in 1770, mentions putrid puerperal fever as extremely common in Bengal. The Hindoo women, who, at the time of their confinement, are, in many cases, placed apart in small, damp, ill-ventilated rooms, artificially heated, are still very liable to puerperal metritis, pelvic cellulitis, and peritonitis. History contains only too abundant evidence of the fact that, in mediæval England, the lives of even royal ladies were frequently sacrificed under a similar practice of "lying-in" in unventilated castle chambers, over-heated and scrupulously closed against every in-draught of pure air. This was, probably, one of our many customs learnt in the Crusades. In 1836, the surgeon to the Calcutta General Hospital wrote[28]—"Puerperal Fever, in its severe form, is a rare disease in Bengal." Mackinnon, who, previously to the appearance of his great work, was stationed at Tirhoot, Dinapore, and Cawnpore, spoke of true puerperal fever as rare—he believed totally absent—in India.[29] Until of late years, within my knowledge, Lower Bengal was nearly free from erysipelas, and puerperal fever was not common in the obstetric wards of our hospitals. When erysipelas became very prevalent in Calcutta, in June, 1874, I inquired of Dr. Charles whether there was any puerperal fever in his wards. He replied that they were particularly free from this disease. Shortly afterwards, so many cases occurred among his patients, that I had to provide accommodation for him in a separate building.

Dr. De Renzy states[30] that Abbotabad, in the Punjaub, has long had a bad reputation for puerperal fever. He thinks this may be attributed to the practice of washing the Europeans' clothing in the watercourse which is the natural drain of the native town.

Malarious Post-Partum Fever.

At Chittagong, thirty years ago, and also in Calcutta subsequently, I had in my practice frequent illustrations of the fact that there, soon after delivery, both European and native women, often get fever, generally with arrest of the milk and lochia. At first these symptoms were equally terrifying to the patient and the physi-

cian ; but I soon found that no other severe symptoms were developed, and that quinine speedily restored health. I had many of these cases ; but not one that did badly or long refused to be controlled by the specific.

I was much interested, in 1880, by reading[31] the report of a discussion upon this fever as it occurs in the neighbourhood of New York. It is called by Professor Fordyce Barker "Puerperal Malarious Fever." As in India, it stands quite apart from all the forms of deadly "Puerperal Fever." I prefer my own nomenclature for the Bengal malady. Professor Barker observes that it may occur from twenty-four hours after a normal labour up to completion of puerperal recovery. Only one of his seventeen cases was fatal, on the 47th day after confinement. He gives half-ounce doses of Warburg's Tincture every four hours until the fever is entirely abated, continuing it, in diminishing doses, until convalescence is perfectly established. He finds it a far more effectual and speedy remedy than the largest doses of quinine. In the discussion which followed the reading of Professor Barker's paper, Dr. Jones, who lives in a malarious district, said that he gives a dose of quinine on the day following confinement. Dr. Lusk considered that it is needful to remove these women from lying-in hospitals, as puerperal peritonitis and cellulitis begin to appear in other cases. Dr. Barker puts his patients on quinine immediately after confinement, from January to June, and continues it for ten days. Dr. Emmett referred to cases in which there were uterine hæmorrhage, sub-involution, cellulitis, &c., in women who had been living in malarious districts, and which could not be cured except by quinine. Professor Barker does not mention the lochia. Dr. Gillette speaks of "the purity of the lochial discharges" as a diagnostic point in these cases. In the Bengal disease, as I saw it, the lochial discharge was checked until the fever abated.

In 1839, Dr. Duncan Stewart, then of Calcutta, published[32] some very important remarks upon the predisposition of pregnant women to fever, and upon the great danger of *Bengal fever when occurring late in pregnancy*. He shows that it generally happens that, when labour occurs in the course of fever, it is *premature*. He cites the following striking observation from Twining :— "I hardly deem any part of the observations I have to offer concerning the peculiar nature and treatment of the remittent fever of the rainy season in Bengal of more importance than the caution I have now given respecting the hazard of either bleeding or applying leeches at a late stage of the paroxysm, after the disease has been returning daily above a week, and when the patient is much exhausted. I have met with several instances where the application of leeches was, from trivial causes, delayed for three or four hours after they were ordered, and then put on towards the conclusion of the paroxysm when arterial action was subsiding—the patient being in a state of languor and anxiety, and the skin perspiring freely—and death has been the consequence.

"If," says Dr. Stewart, "such results have followed the loss of a minute quantity of blood under ordinary circumstances, will it surprise any one that the occurrence of even natural labour at the end of a paroxysm of fever should be matter of more than ordinary anxiety, or that the abstraction of so large a portion of blood as must attend even the best conducted delivery should, at such a time, be eminently perilous ?" I have seen grave remittent fever, in Bengal, passed through under quinine, by which a cure was effected some weeks before delivery, with perfect immunity both to mother and child, but a more anxious case for the physician it is hardly possible to conceive.

[31] *Med. Times and Gazette*, March 20, 1880, p. 327.
[32] *Ind. Jour. of Med. and Phys. Sc.*, vol. iv., p. 587.

I cannot find a more appropriate conclusion, not only for this particular subject, but also for my review of Indian Paludal Fevers, than the following striking passage from the writings of Dr. Barnes :[33]—"The pertinacity of ague is well known. We are accustomed to see marks of its abiding influence long after the fits have ceased, long after the patient has lost all consciousness of suffering. But I have seen ague fits reproduced years after under the condition of pregnancy. We cannot fail, then, here to see, that there lingers somewhere in the system some change, the stamp of the original disease ; and we may fairly presume that this change is in the nervous centres. Perhaps the precise organic change may long baffle the skill of the microscopical analyst to detect ; but there it is proved by anticipation to exist, as real a thing as the planet discovered by Adams and Leverrier before it was seen by mortal eye through the telescope."

Note on the Subcutaneous Injection of Quinine in Malarious Fevers.

My friend, Brigade-Surgeon J. B. Scriven, read a highly valuable summary of his large experience in this practice at the International Medical Congress at Amsterdam last September. He shows that the use of a solution of thirty grains of quinine in half an ounce of water, with eight or ten drops of dilute sulphuric acid, was potent in checking the fever, but led to numerous ill-results, such as abscess, ulceration, and tetanus. Consequently, this mode of using quinine was prohibited in the European army in India. Mr. Scriven also abandoned its use in natives for the same reason. Subsequently, Dr. J. E. T. Aitchison and Mr. Scriven had remarkable success in the use of a solution containing quinine a drachm, tartaric acid half a drachm, and distilled water sufficient to make three fluid drachms, Buzzard's syringe being employed. He was careful to select a spot, usually at the back of the fore-arm, where no cutaneous vein became visible after grasping the arm above the elbow, and to introduce the point of the instrument with the opening *away* from the skin, so that the solution should escape towards the muscles instead of towards the surface. He employed this method for four years, in about eighty cases, without a single instance of tetanus, abscess, ulceration, sloughing, or any untoward result. As a rule, a little inflammation of the fore-arm followed. The arm being kept in a sling and cold lotions being applied, this subsided in a few days. In an adult, Mr. Scriven injects from fifteen to twenty minims of the solution—fifteen minims containing five grains of sulphate of quinine. In one case, of a child under a year, he injected seven minims. He especially recommends this practice in cases in which death is imminent, and a remedy is necessary that shall produce a rapid and decided effect. Mr. Scriven informs me that he has adopted this course "in several cases of fever in which there was great exhaustion, the surface covered with a cold perspiration, the pulse scarcely perceptible, and every appearance of approaching death, and these cases have recovered without any recurrence of the fever."

(*Malarious Fevers concluded.*)

MENSTRUATION IN ST. PETERSBURG.—Dr. F. Weber publishes, in the *St. Petersburger Medicinische Wochenschrift* (November 7th, 10th, and 14th), an elaborate statistical paper on the condition of menstruation as observed among the women of various classes in that capital. The paper is far too long for our purposes, but we may advantageously direct attention to it as a document likely to be highly interesting to those engaged in similar researches.

CRITICISMS ON SIR W. GUYER HUNTER'S VIEWS WITH REGARD TO THE OUTBREAK OF CHOLERA IN EGYPT.

I.—By Surgeon-General DE RENZY, C.B.[1]

The evidence adduced by Surgeon-General Hunter seems to me altogether inadequate to warrant the conclusion that cholera has been endemic in Egypt since 1865. The facts he brings forward amount simply to this, that diarrhœa has long been a very prevalent and fatal disease in Egypt, and that he had received reports of 23 isolated cases which bore a strong resemblance to cholera, and which had occurred in the interval between 1866 (the year following the epidemic of 1865) and 1882. Of the 23 cases reported, four proved fatal and nineteen recovered, an extremely low rate of mortality for true cholera. The details of the cases are most meagre, and are supplied by the memory of the reporters, unsupported by written notes made at the time. Evidence of this kind may be sufficient for those who, like Sir W. G. Hunter, believe that cholera is endemic in England, but it will not satisfy those who do not think with him on that point.

Judging from the behaviour of cholera in India, it seems to me quite incredible that, if the disease had really been endemic in Egypt, Sir W. G. Hunter would have failed to discover evidence of some explosive outbreaks having occurred in different places in the long interval between the cessation of the epidemic of 1865, and the close of 1882. Egypt seems to be in a state very similar to that of India, as regards the absence of skilled medical men in the villages. I should not, therefore, expect to be able to get good professional accounts of village outbreaks, but surely, if cholera epidemics had occured with the explosive suddenness which is so characteristic of the disease, the fact would have left its mark in the death-registers. I have often been able, by taking this characteristic as a clue, to bring to light outbreaks of cholera in the Punjâb, which, from the timidity of the people, had not been reported as such, and which had escaped notice. Is it credible, that if such outbreaks had occurred in Egypt, Sir W. G. Hunter would have to rely upon the meagre details of his 23 isolated cases to support his conclusion? Even if there were no death-registers, I cannot believe, that if cholera explosions had occurred, the village memory would have been unable to give some account of them, for the minds of peasants are singularly retentive of the impressions made by such occurrences. In the Punjâb, I have been able to get information of cholera epidemics that had occurred thirty years before the British annexation of the province. The fact that Sir W. G. Hunter had heard nothing of such explosive outbreaks, appears to me very strong evidence that cholera was not endemic in Egypt, for if it had been, the people lived in such utter defiance of sanitary laws, that the disease must have given far more decisive evidence of its presence than Sir W. G. Hunter's 23 isolated cases afford.

Sir W. G. Hunter says, "Cholera is recognised by a certain group of symptoms, and it is merely begging the question to say that a particular case though presenting all the phenomena of cholera cannot be cholera because it does not propagate itself." It appears to me that Sir W. G. Hunter does not make sufficient allowance for the difficulty of diagnosing cholera. It is one of the most difficult of all diseases to diagnose. It sometimes occurs in so mild a form that it does not prevent the patient from attending to his business. It is then regarded as simple diarrhœa, and its true nature is only discovered when some persons who have been in contact with the patient take the disease in an aggravated form. As an illustration of the difficulty of diagnosing cholera, I was once sent for by a very experienced practitioner to see a case in consultation which he regarded as cholera. It turned out to be one of poisoning by arsenic. There are many causes which produce symptoms very like those of cholera. I remember a sergeant of the 101st Regiment, at Multan, who was supposed at first to have cholera. It turned out that he was poisoned with slightly putrid salmon. The medical man who was taken in in this case was one of the ablest medical officers that the Indian Medical Service has ever had, and a man of great experience. Putrid meat, putrid fish, putrid fruit, and foul water often produce symptoms hardly distinguishable from those of cholera. Further, every medical man of large Indian experience must have seen cases of intermittent fever which, in the cold stage, are remarkably like cholera. Such cases used to be very common at Peshawar. But though the outward phenomena were almost identically the same as those of cholera, there must be an essential difference between them, as is shown by the fact that fevers with choleraic symptoms have a small rate of mortality and do not occur in batches.

Surgeon-Major McNally's evidence, quoted by Sir W. G. Hunter, appears to me of great interest and importance, as giving a very probable clue to the true source of the epidemic. Dr. McNally states that diarrhœa with vomiting had existed since January, 1883, and had proved fatal to 200 persons in the neighbourhood of Zagazig, and that great mortality from cholera had occurred at Chibin-el-Kom previous to the recognition of the disease at Damietta. In one village near Binha "there had been fifteen deaths a day." Here we have evidence of one of those explosive outbreaks I have already referred to.

Now, in connection with this evidence, it is necessary to remember that towards the close of 1882 there had been a severe epidemic of cholera at Mecca, and doubtless there were numerous bands of Egyptian pilgrims there during the outbreak. These pilgrims would have returned to Egypt about the time that Dr. McNally says deaths from diarrhœa with vomiting became rife at Zagazig. Sir W. G. Hunter appears to have made no enquiries about these pilgrims. Indeed, he entirely ignores the Mecca epidemic as a possible source of the Egyptian epidemic. Sir W. G. Hunter's reports are of the greatest value, on account of the light they throw on the sanitary state of Egppt, but I think he was too easily satisfied that the epidemic had not an external origin. When the first suggested clue to an external source failed with the demonstration that the epidemic could not possibly have originated from the stoker of the steamer *Timor*, he appears to have given up the search for an external origin altogether, and to have adopted the conclusion that the gross neglect of sanitary measures afforded a full and sufficient explanation of the epidemic. It may be that an investigation of the condition of the returning pilgrims would have thrown no light on the origin of the epidemic; still I think it is greatly to be regretted that the investigation was not made. Indian experience shows what apt media pilgrims are for the dissemination of cholera, and Egyptian pilgrims I imagine do not differ greatly from Indian pilgrims.

Indian pilgrims have a strong prejudice in favour of carrying home with them the clothing of relatives or friends who die in their company on a pilgrimage. If the Egyptian pilgrims have the same prejudice, the fact would go far to explain the introduction of the

[1] Communicated to the Epidemiological Society.

cholera virus from Mecca into Egypt. The sanitary authorities at Suez would doubtless say that the quarantine arrangements at Moses Wells exclude the possibility of the virus being introduced by pilgrims. It would have been very satisfactory to have had a detailed account of these quarantine arrangements founded on personal observation by a man of Sir W. G. Hunter's experience and penetration. My own experience has entirely destroyed my faith in the protective value of quarantine. Quarantine, in my experience, is a powerful means of throwing doubt and obscurity on the origin of epidemics of cholera, but no reliance can be placed on it as a means of preventing them.

Supposing the cholera virus to have been brought into the Lazaretto by the pilgrims, the railway to Zagazig afforded the means of conveying it in a few hours to that place. It may be said that if the virus had been introduced by pilgrims, its presence would have been felt long before the explosion at Damietta. But does not Dr. McNally's report show that some unusual force had begun to act on the health of the people long before the date of the Damietta outbreak. In the Punjâb, where the disease can no more be said to be endemic than it is in England, it often takes several months to extend itself over the province after its virus has been introduced through the agency of pilgrims or other means.

In conclusion, I submit that the evidence adduced by Sir W. G. Hunter is not sufficient to warrant the conclusion that cholera has long been endemic in Egypt, nor to exclude the probability that the virus of the disease was introduced through pilgrims from Mecca.

II.—By Brigade-Surgeon C. A. JESSOP, M.R.C.P.[2]

With the kind permission of the President and members of this Society, I should like to say that, while agreeing with Sir W. G. Hunter as to the necessity of improved sanitation for stamping out cholera and relying less on quarantine, I, nevertheless, venture to believe that when cholera becomes epidemic some espionage is peremptorily required. For, although cholera does not present the virulence of direct contagion characterising small-pox, yet, like enteric fever, a patient is capable of giving the disease by his alvine evacuations, and of generating around him a "halitus," which has a septic influence on persons in whom their is a receptivity for the poison. This "halitus" increases in virulence by collecting cases into one centre, and may produce an epidemic when telluric and atmospheric conditions are combined; further, it is capable of conveyance by healthy foci.

In the course of six epidemics I remember two cases of communication from sick to healthy. One was a corporal of the Scots Guards, in the Crimea, who contracted disease from hand-rubbing patients. The second, an orderly of the Medical Staff at Hong Kong, under the same circumstances. I may just observe that cramp is readily controlled, either by turpentine internally, or chloral hydrate subcutaneously, and thus the risk hand-rubbing entails is avoided.

The epidemic at Hong Kong began among troops on passage from Canton, 16th June, 1858. They embarked at 6 a.m., proceeded down river, nine miles, in gunboats, to Whampoa, and were crowded on board s.s. *Adventure*, with high bulwarks. The weather was intensely sultry and hot. Many sunstrokes had occurred at Canton, but there was no cholera among European or native troops. We arrived at Hong Kong, 60 miles off, the same evening. In the course of the afternoon, cases of fever, both in the cold and hot stage (chiefly the latter) occurred, attended with vomiting, purging, cramp and cyanosis. Cholera was not thought of. It was only when the dejections became rice-water in character, with husky voice and collapse, that such a suspicion arose. Cases increased, and were sent ashore. The troops disembarked on the 18th, and the vessel was fumigated, and they re-embarked on the 22nd, bound for the Peiho. Surgeon Dawnay also re-embarked, and ultimately died of the complaint at sea. The outbreak at Hong Kong was not of long continuance. The number of admissions are unknown; there were thirteen deaths among Europeans, and some among gun Lascars. I attributed the epidemic to exposure, over-crowding, fatigue and fasting, with probably impure water, drunk whilst the troops loitered in a hot sun at Whampoa. It was clearly an epidemic arising *de novo*.

At Mhow, a cholera epidemic occurred in June, 1865, and a thick, yellow atmosphere prevailed; in my regiment there were five admissions and two deaths; several among the native followers; one of the cases was my surgeon, ultimately invalided for cardiac debility consequent on this complaint. The epidemic died out in consequence, as it appeared to me, of the hot, dry, strong breeze which prevailed at that season.

At Meerut, in August and September, 1872, epidemic cholera occurred, heralded by dengue. The summer had been close and oppressive with the usual fever cases. Suddenly, at this time, every case assumed a typhoid character. Dengue came first, then cholera selected its victims. In my own regiment I had five fatal cases of typical cholera. The malign influence filled the hospital with cases of pneumonia and fever with typhoid symptoms, and cerebro-spinal fever followed by acute dysentery. Dengue was epidemic the whole time. Although deaths were popularly put down to cholera, yet pathologically, as far as my own regiment was concerned, they died from other causes, for with the exception of a woman, who died from cholera, and a man from low fever, I made *post mortems* in all cases, and examined the spinal cord in five out of nine. I did not allow cholera cases to be treated in a general ward, but in tents, to avoid risk and alarm to other patients dangerously ill, who in their turn were removed to tents.

My experience of cholera coincides with that of Dr. Bellew, quoted by Dr. F. N. Macnamara, at page 441, of his "Himalayan India, its Climate and Diseases," 1880.

III.—By THEODORE ACLAND, M.D. Oxon.[3]

Dr. Theodore Acland expressed his admiration of the indefatigable manner in which Sir W. G. Hunter had worked to collect the information contained in his reports, and supplemented his description of the sanitary conditions prevalent in the larger towns by narrating cases which had come under his own observation; but the speaker could not agree with Sir W. G. Hunter in thinking that, because no particular organism capable of transmitting the disease had been demonstrated, therefore cholera was not contagious; and he instanced the case of syphilis and scarlet fever, both in their several ways virulently contagious, but in neither of which a "contagium" had been isolated. He then referred to enteric fever—a disease which, as a rule, is spread by the contamination of potable fluids by the dejecta of persons suffering from the disease, yet capable also of being directly communicated to those brought into close contact with the sick, such as nurses. The general wave of the epidemic had been traced by Sir W. G. Hunter; a local observer could only give an account of some of those side eddies

[2] Communicated to the Epidemiological Society.

[3] Abstract of a speech delivered at the Medical Society, on March 3rd, 1884.

which, although modified by the same laws, are without doubt subsidiary to the more general conditions affecting the whole course of an epidemic, such as temperature, moisture, or other climatic conditions. There were reasons for supposing that cholera could be spread from one infected district to another, or from one body of men to another, by means which were in some measure under control. In support of this view, the following facts were adduced :—

1. That of a total of 86 cases of cholera, occurring in the Egyptian army, no less than 59 were in two battalions, the 6th, and the artillery, which were situated, the one at Jörah, on the east, the other at Gizeh, on the west bank of the Nile, to the south, and, therefore, to leeward of Bulaj, the most infected district in Cairo. The two regiments were some miles apart, they drew their water supply from above Cairo, and no case occurred amongst the troops at Jörah, until after the evicted and cholera tainted inhabitants of Bulaj, had been deported to a spot about four miles directly to windward of their camp. On the other hand, amongst the whole seven regiments quartered on the north, and, therefore, to windward of Cairo ; there were altogether a less number of cases, than in either of the two battalions which had been stationed to leeward.

2. That at the time of the epidemic, there were in Egypt, 188 officers attached to the English army, and 196 men belonging to the Army Hospital Corps, but while only three of the former suffered from cholera, no less than eighteen of the latter were attacked, a number three times as great as the average for the main body of the troops, and six times as great as that of the officers, who were exposed to the same climatic conditions, but who were not brought into such close contact with the sick.

3. Lastly, as regards the Egyptian army, of four English officers much engaged in the hospital, one had suffered severely from cholera, another from vomiting, purging, and cramps, but no collapse, and a third, after severe diarrhœa, had a well-marked attack of enteric fever. Of the native officers, two only were attacked, but they both belonged to the artillery, and had both been active in bringing their sick companions to hospital. From these, and similar facts, the speaker thought that within the general wave of an epidemic, there existed side currents, due to the presence of suitable local conditions, which caused the spread of the disease from man to man in spite of the absence of proof of the existence of a definite contagium.

ON THE YELLOW PIGMENT FOUND IN THE INTESTINES IN CASES OF ARSENICAL POISONING.

By J. CAMPBELL BROWN, D.Sc., and EDWARD DAVIS, F.C.S.

It has frequently been recorded that a yellow colour has been obtained on the stomach and intestines of persons who have died from arsenical poisoning, after long interment.

It is not always stated to what this yellow colour is due ; but it has sometimes been attributed to the formation of sulphide of arsenic. Thus, in "Taylor on Poisons" the following passages occur : — "White arsenic slowly becomes changed to yellow sulphide, by the solution of sulphuretted hydrogen in the decomposition of the stomach or of its contents. It then leaves a deep yellow stain through the coats, and appears on the external surface." "In Mrs. Smith's case, the sulphuret of arsenic was discovered in the stomach fourteen months after interment."

"In the case of the Cheshams, the coats of the stomach were in both instances deeply dyed with large patches of yellow pigment, nine months after interment."

"In some cases the coats of the stomach and intestines, the liver, diaphragm, and even the bones of the spinal column, may be thus deeply stained of a yellow colour."

In "Reports of Trials for Murder by Poisoning," by Lathom Browne and Stewart, the following passage occurs :—

"In bodies long buried the arsenic is often converted into the sulphide by putrefaction, and then appears as a yellow coating."

No proof has ever been adduced, so far as we are aware, that the yellow substance is really sulphide of arsenic.

We have recently had an opportunity of examining a yellow substance, found in the circumstances referred to, in two bodies exhumed in January last, and think it desirable to place our observations on record.

One of the bodies was that of a young man, aged 22, which had lain in the grave upwards of three years. It was in a state of good preservation, the stomach, intestines, and viscera having decreased in size without losing their usual form and appearance. From the whole of the abdominal viscera, $3\frac{1}{4}$ grains of arsenic were extracted. The whole of the small intestines were coated internally with a bright yellow pigment, resembling mustard, as were also the greater part of the mesenteric vessels. The colour was visible through the walls of the intestines. It reminded one of orpiment, and in some places realgar. The other body was that of a girl, aged ten years, which had been in the grave more than thirteen months. The viscera were in a good state of preservation although contracted. From the abdominal viscera one grain of arsenic was extracted. The bright yellow pigment was distinctly present in the intestines and mesentery, although the quantity was not so great as in the previous case.

In another body, which had not been buried, no yellow pigment was found, although there was more than a grain of arsenic in the intestines.

In a fourth body, which had been in the grave less than a year, but in which the quantity of arsenic was probably not more than half a grain, the yellow pigment was perceptible, but the quantity was very small.

We collected a considerable quantity of the yellow pigment, weighing in the moist state between twenty and thirty grains. It was carefully tested for arsenic, and was found to contain no appreciable quantity of the metal. It certainly was not sulphide of arsenic. Nitric acid produced a play of indistinct colours similar to those produced in bile by nitric acid.

We found that the yellow pigment was readily soluble in chloroform, forming a bright and clear yellow solution ; less soluble in alcohol ; slightly soluble in strong ammonia, reprecipitated by hydrochloric acid ; and insoluble in water.

The chloroform solution left, on evaporation, a deep yellow residue. This yellow residue was reddened by strong hydrochloric acid, while nascent hydrogen from zinc and hydrochloric acid discharged the colour and dissolved the residue. Nitric acid converted it into a purple, then red, then brown substance. Sulphuric acid gave a temporary violet colour, quickly becoming brown. Sulphuric acid and pure sugar gave the violet-purple tint characteristic of Pettenkofer's test. The colouring matter, therefore, appears to resemble one of the products of decomposition of bile pigment.

These results do not prove that it is actually formed from the bile, but that it is composed of one or more organic substances, one of which is somewhat similar to one of the pigments said to be formed by reducing agents on an alkaline solution of bile.

REPORTS OF

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

GUY'S HOSPITAL.

CASES OF DIABETES, TREATED WITH NUX VOMICA AND MINERAL ACIDS.

By Dr. S. WILKS, F.R.S.,
Physician to the Hospital.

Case 1 (reported by Mr. P. James).—James W., aged 28, admitted March 13th, 1878. In December of the previous year he found he was passing an excessive amount of urine, eight to ten pints daily. He also found himself getting weaker and thinner; although his appetite increased, his weight fell considerably below that which it had been—twelve stone. He had constipation and other symptoms which usually accompany diabetes.

On admission, he was found to be organically sound, but thin. He was passing eight and a half pints of urine daily; his weight was eleven stone. He had had diarrhœa for a few days; for this a little opium was given, and when the diarrhœa was stopped he was put upon dilute sulphuric acid, cardamoms, and nux vomica, and was ordered the usual diabetic diet—that is, abstinence from farinaceous food. He gradually improved in strength, although some sugar was still found in the urine, the amount of which, on April 17th, was five pints.

May 5th.—Three pints of urine were passed; the patient is gaining in strength and weight.

May 16th.—Urine reduced to two pints seven ounces.

May 25th.—He left the hospital, the average amount of water daily being three pints of sp. gr. 1030, with a considerable amount of sugar. The patient asid he felt quite well, and weighed 171 pounds being, he said, three pounds heavier than he had ever been before in his life.

Case 2 (reported by Mr. H. P. Keating).—Wm. S., aged 22, a grainer, admitted May 5th, 1882. In the beginning of April he found he was suffering from excessive thirst, and noticed that he passed a large amount of urine. This continued up to the date of his admission to hospital. He had also been getting thin, although very hungry and eating well. The urine was said to contain more than 40 grs. to the ounce, and his weight was 121 pounds.

On May 14th, the urine was five pints in 24 hours, of sp. gr. 1037. He was put on the diabetic diet—animal food with green vegetables, with no bread or other farinaceous substances, and ordered for medicine Acid. Nitric. dil. mx., Tr. Nucis Vom. mxv., Tr. Aurantii ʒss., Aq. ʒj. ter die.

May 22nd.—Patient said he felt much better, and his weight was 124½ pounds.

May 23rd.—Urine 40 oz., sp. gr. 1040. Quantity of sugar per oz. 13·6 grs.

May 30th.—Patient's condition continued about the same. His weight was 129 pounds.

June 6th.—He expressed himself as feeling stronger and better. Weight 132 pounds.

June 20th.—Urine the same, 40 oz., sp. gr. 1040. Weight 135 pounds. He was then ordered, besides his medicine, Acid. Sulphurosi ℥j., Syr. Aurantii ʒss., Aq. ad Oj. for a drink during the day; and the medicine was changed to Acid. Sulph. dil. mx., Liq. Strychniæ mx. Inf. Calumbæ ʒj. ter die.

June 27th.—The urine is passed in somewhat larger quantity, and of less specific gravity. He has continued the acid drink which (as will be seen) contained a small amount of syrup. His weight was 138 pounds, and he expressed himself as much stronger and in better spirits.

July 12th.—His weight was 142 pounds.

July 22nd.—Urine three pints, sp. gr. 1030, 11 grs. of sugar to the ounce.

July 28th.—Weight 144 pounds. He left the hospital this day, having gained in weight 23 pounds during his stay.

After leaving the hospital he went to work, and did not, he said, remain strict to the diet as had been advised; but was not particularly thirsty until March of the following year, 1883, when he observed his legs swollen. He was very thin, his breath had a marked diabetic odour, his urine contained besides sugar a little albumen. He also had a large boil on his cheek. He was soon after seized with pain in the abdomen and in the side, and died suddenly.

The *autopsy* revealed no marked lesions.

Case 3 (reported by Mr. A. Linnell).—Wm. N., aged sixteen, a painter, was admitted on February 6th, 1883. For two or three months he had been suffering from continual thirst, craving for food, loss of flesh and strength. He had also during that time passed large quantities of urine. He was a pale, thin, weakly looking lad; urine, sp. gr. 1040, and loaded with sugar.

He was ordered the diabetic diet, and for medicine Acid. Nit. dil. mx., Tr. Nucis Vomicæ mx., Tr. Chloroform. mx., Aq. ʒj. ter die.

February 15th.—He has passed 88 oz. of urine in the preceding 24 hours, sp. gr. 1040; and his weight is 78 pounds.

From this date the amount of sugar steadily diminished, although varying in amount from time to time.

March 20th.—Amount of urine passed 70 oz., and sp. gr. 1030.

On April 4th, a little more than this. At the beginning of June the average quantity was 40 oz., and sp. gr. 1030.

He had been gaining flesh steadily since his admission, and on June 14th, when he left the hospital, he weighed 91½ pounds. His urine was 44 oz. in quantity, with a sp. gr. 1030.

Remarks.—The above cases are samples of a class in which, I believe, the treatment adopted was attended by a real and substantial benefit; whether indeed by any direct influence on the disease itself, or whether by only counteracting its effects I will not venture to say. As is well known, a very large number of remedies have been tried in diabetes, more especially those which from their supposed physiological action, might be considered instrumental in getting at the root of the disease, either through the nervous system or by affecting chemically the composition of the blood. None of these, however, have shown themselves to be of any value. The only remedy indeed for which universal consent has pronounced a favourable verdict is opium; but it is not maintained, I believe, that this drug is curative in the ordinary acceptation of the term. It is possible that opium has no special action on the disease, but that its good effects are due to the general sedative influence which it exerts over every function of the body. It arrests physiological action, both of a normal and abnormal kind, and therefore has a power over such a disease as diabetes, whether we regard this with Bernard as due to an intensified physiological action, or with Pavy as a distinct process of a true pathological character. For my own part, in considering the best remedies for diabetes, and putting aside opium and its substitute codeia, I have always regarded those as the most useful which have long possessed a repute in stomach and liver affections. For example, nux vomica has had a universal reputation for its power in atonic,

and some other forms of dyspepsia, whilst the mineral acids in like manner have preserved their character for good both in hepatic and gastric disorders. These remedies and analogous ones I have usually given in diabetes, and, in my experience, with considerable more advantage than soda, ammonia, iron, and many other drugs. I have given nitro-hydrochloric acid with so marked an improvement in the symptoms, that I have had a suspicion whether the mineral acids may not have had some special chemical action over glycogenic substances, or in some other way affected the metabolic processes which are in operation. With this idea I have made patients drink in considerable abundance sulphuric and sulphurous acids over and above the smaller dose contained in their medicine, and the reader will see for himself by referring to the reports of cases with what effect. Besides the above reported examples I have had several others, both in hospital and private, which appear strongly to vindicate my statement as to the value of the remedy, but I consider these three cases are sufficient to show that my plan requires much more extended application or trial. An easy explanation for the good result obtained may be found in the supposition that the patients ate more food whilst under treatment, a good animal diet being substituted for that which before ran over off as waste; or if this did not hold good, and the patients merely abstained from taking glycogenic substances, that the arrest of the sugar-forming process, by cutting off the supply of the material, was in itself a positive advantage, since the circulation of the sugar in itself is detrimental to the healthy functions of the body. For my own part I cannot think these explanations sufficient to account for my results, and therefore believe that a positive good was effected by the remedies; the patients seemed to be in better condition and were gaining more weight, although they still excreted a large quantity of sugar, than others who took opium, and in whom the sugar was reduced to a minimum.

Of course, when speaking of diabetes, I refer to the simple form of the disease in young people, for the glycosuria of older persons seems to be of an altogether different nature; at all events as regards its results. If a summary be made of all cases indiscriminately, no conclusions of any value can be arrived at, seeing what a different course diabetes pursues in the young and old. In the former the tendency is sooner or later towards a fatal termination, whilst in the latter the presence of sugar in the urine is often found in those who are suffering from mere dyspepsia or gout. I have in my note-books cases of many persons, mostly men, who have been of a gouty constitution, have been free-livers, and in whom sugar has frequently appeared in the urine. Sometimes this has alternated with a discharge of free uric acid. I occasionally see an old gentleman, 70 years of age, who, being tired of dieting, takes ordinary food, and passes a large amount of sugar. This has been going on for some years, and he is in tolerable health.

Medicinal Powders.—M. Vigiér, an able pharmaceutical writer in the *Gazette Hebdomadaire*, draws attention, in the number for February 1st, to the deterioration which medicinal powders have undergone, since, in place of their former pulverisation at the retail pharmacies, they have been prepared in an impalpable form by wholesale establishments. He affirms that inferior products are frequently thus prepared, and look very satisfactory to the eye, while containing too little of the active principle. Aromatic substances, also, undergo deterioration by the preliminary desiccation they are subjected to prior to this minute pulverisation. Such pulverisation is not, in fact, required, and may even be detrimental; and the Committee of the Paris Codex, entertaining this view, recommend that sieves, having meshes of various sizes, shall be employed in the preparation of different medicinal powders.

Medical Times and Gazette.

SATURDAY, MARCH 8, 1884.

The Government Medical Act Amendment Bill was introduced into the House of Lords by Lord Carlingford early in the week, and was read a second time on Thursday evening. The Bill is exactly the same as it was when it left the Upper House last year, but Lord Carlingford proposes to introduce some amendments in Committee, the chief of which will have the effect of raising the number of the representatives of the Scottish Universities on the general board from three to five. In moving the second reading, Lord Carlingford said that the object of the Bill was to give greater security to the public that every practitioner should be reasonably qualified to practice. This was a matter of the least importance to all, and one which greatly concerned the credit of the medical profession. We are glad to see that on this point Lord Carlingford does not accept Professor Huxley's contention, that the objects of State intervention in medical affairs is solely to provide Government with competent officials and reliable witnesses in courts of law.

With the exception of the above but little of medical interest has been brought forward in either House of Parliament since our last. On the 28th February, Mr. Gibson asked "whether any steps had been taken by Her Majesty's Government since August last, to lessen the dissatisfaction existing in all ranks of the Indian Medical Service." To this, the Under-Secretary for India, Mr. J. K. Cross, replied that, "as he had said last year," in order to remove gradually the disadvantages of there being in that service more officers than there were substantive posts, the number of annual appointments had been reduced to the lowest pitch compatible with justice to students, and the future efficiency of the Department. This remedial measure was being continued; only ten appointments had been made to the Service last year, and this year also only ten would be made; and it was not intended to take any other steps to meet the grievances complained of. Mr. Cross' reply is anything but a satisfactory one. It in no way meets, in fact it entirely ignores, the great grievance of those junior officers, who, after several years' service, are still drawing "unemployed" rates of pay, even when in fact "employed." They justly complain that the expectations held out in the official memorandum by which they were induced to enter the service have not been fulfilled. That memorandum was withdrawn last year, and an "amended" one issued in place of it; but neither this proceeding, which is tantamount to a confession that the terms of the former document were not to be relied on, nor the diminution in the number of annual appointments in any degree remedies the injustice under which the junior officers labour. Mr. Gibson gave notice that he would call attention to the subject at as early a date as possible.

Mr. Mundella has received from the London School Board some reports on cases of alleged over-work in School Board schools, and is expecting other reports. When received, all the reports will be laid on the table of the House of Commons. Mr. Mundella is extremely unwilling to believe that there can be anything like over-work in any of the Board schools. He has insisted that if such a thing does exist, it must be rare; and it must be the fault of the teachers, or of the managers; but certainly not the fault of the Code. The New Code, he persists, is not only not more severe, but it is less so than the former Code was; and the intention, and he believes the effect, of it is to relieve young children from pressure of work. Moreover, the Department, he declares, expressly empowers teachers and managers to withdraw delicate children from examination, and steadfastly sets its face against everything approaching over-work and pressure. All this may be true, but the Department does not know, or has not taken care to remember, that what is really light brain work for healthy, well-fed children, brought up in decent surroundings, becomes very severe work for ill-clothed, half-starved children, dragged up in misery and poverty. And, further, the system of payment by results adopted by the Department, inevitably excites, if it is not meant to incite, the managers and teachers to work the schools at high pressure. We are glad, however, to learn from Mr. Mundella that the educational authorities are not quite satisfied with the present state of things, and are considering how they can best protect weakly children "from being over-worked during the year previous to examination." That will be a gain, but it will not be enough; all the children, and the pupil teachers, need protection from over-pressure.

The Secretary of State for War was asked on Monday last, whether any steps were being taken to carry out the recommendations of Lord Morley's Committee, with respect to the closer union of the Army Medical Department and the Army Hospital Corps. Lord Hartington's reply was as unsatisfactory as possible. He said, he hoped, in introducing the Army Estimates, to make a general statement of the intentions of the Government with regard to the recommendations contained in the report referred to. It will be remembered that last year the Government managed to escape all serious discussion in the House of Commons on those parts of the report dealing with the services of the Army Medical Department, by promising that opportunity for such a discussion should be given when the Army Estimates came before the House. But the vote for medical establishments and services was not brought on till at the very end of the session, and then Lord Hartington said, that it was proposed to go through the recommendations made by Lord Morley's Committee as soon as possible after the recess, and to consider to what extent they could be adopted; and he advised the postponement of all discussion until the action the Government might propose to take upon the report should be brought forward "early" next year. But "next year" has come, and Lord Hartington is still unable to make any definite statement whatever on the matter. He only "hopes" to make a general statement when the Army Estimates are introduced. Is any member of the Ministry ever "able" to give a plain answer to a plain question? Inability, in that respect, seems to be their most prominent characteristic.

The resolution proposed by Mr. Arthur Balfour in the House of Commons, on Tuesday, in favour of loans being made by the Public Works Loan Commissioners, for the improvement of the dwellings of the working classes, on easier terms than is at present possible, excited a long and not uninteresting discussion. To those, indeed, who had hitherto troubled themselves very little, if at all, about the manner in which the working classes are housed, the speeches made on this occasion must prove very instructive as well as interesting; but they contain nothing new to our readers; nothing new as to the magnitude of the evils that have to be remedied; nothing new as to the difficulties that have to be overcome; and nothing new, that is practicable, as to the means of overcoming them. Sir Lyon Playfair pointed out that one of the greatest difficulties in the way of remedial measures is the system of land tenure, by which numerous lessees may in succession take the responsibility as to the condition of buildings off the shoulders of the ground landlords; and that another and still greater difficulty is the want of unity of local government. This may be very true; but we trust that no one will think it desirable or possible to postpone the improvement of the dwellings of the poor till the land tenure has been reformed, and a Lord Mayor reigns over the whole metropolis. Sir Lyon Playfair gave much information respecting the historical side of legislation against overcrowding, and quoted very interesting statistics to prove how London in general has improved, and is now improving, in healthiness. Mr. A. Balfour also pointed out that in not a few respects the condition of our towns and cities has improved immensely during the last 40, 100, and 200 years; and Sir Charles Dilke, in his turn, remarked that the improvement has not been universal, and that while some districts have become healthy and less crowded than they were, others are as overcrowded as ever, or even more so than before. Sir Richard Cross, and some other Members, delivered themselves of good speeches; and the discussion ended in—nothing.

The supplementary estimates submitted to Parliament, include the sum of 600*l.* for Surgeon-General Hunter's expenses in connection with the cholera epidemic—not a bad investment either for Egypt and for science.

A general meeting of the Medical Society of London, was held on Monday last, the 3rd instant, for the election of officers and council for the ensuing session. The following gentlemen were duly elected: — President — Arthur Edward Durham. Vice-Presidents—John Brunton, M.D.; Alfred Cooper; Richard Douglas Powell, M.D.; Sydney Jones. Treasurer — Alfred Wiltshire, M.D. Librarian—

William Henry Allchin, M.B., F.R.S.E. Honorary Secretaries — Alfred Pearce Gould, M.S.; James Kingston Fowler, M.D. Secretary for Foreign Correspondence—Sir William MacCormac, D.Sc. Council—Samuel Benton; Thomas Lauder Brunton, M.D., F.R.S.; R. Brudenell Carter; Samuel Cartwright; John Cavafy, M.D.; Henry Radcliffe Croker, M.D.; John Henry Drew; Sir Joseph Fayrer, K.C.S.I., M.D., F.R.S.; Heneage Gibbes, M.D.; F. de Havilland Hall, M.D.; Jonathan Hutchinson, F.R.S.; Edward Lund; Francis Mason; Edmund Owen; Isambard Owen, M.D.; Arthur Ernest Sansom, M.D.; Charles Brodie Sewell, M.D.; Thomas Gilbart Smith, M.D.; William Heath Strange, M.D.; William Henry White, M.D.

From the report of the Council, the Society seemed to be in a very flourishing condition. Reference was made to the new meeting room, and to the other alterations which had been effected on the Society's premises; they were pronounced by general acclamation to meet all possible requirements, and they reflected great credit on the sub-committee, who had carried them out. Sir Joseph Fayrer resigns his chair to Mr. Durham. His year of office has been an eventful one in the annals of the Society; and his successor will have difficulty in surpassing him. After the formal business of the general meeting was concluded, the ordinary work of the evening, viz., a paper on cholera, by Sir W. G. Hunter, was read and discussed. We have so recently referred to this subject, and given the author's views, as expressed at another learned society, that there is no occasion for further detail in this place.

The Pathological Society at their meeting, on Tuesday last, got through an unusually long programme, but no topic of very special interest was raised. Mr. Clutton and Dr. O'Connor exhibited instances of rare diseases, and the papers by Mr. Lane and Mr. Barwell elicited the fact that there is considerable divergence of opinion amongst the members on questions of pathology as well as in other departments of medicine.

The usual monthly meeting of the Obstetrical Society of London was held on Wednesday evening. The chief business of the evening was the discussion of an elaborate and careful paper by Dr. John Williams, on the corroding ulcer of the uterus. This disease, described by Sir Charles Clark, is so rare, that many writers of systematic works on gynæcology, have had to compile their accounts of it without ever having seen a case; and consequently many of them have either omitted it altogether, or confused it with epithelioma. Dr. Williams had been fortunate enough to meet with three cases, to observe them carefully for long periods, and in one of them to examine the affected parts *post mortem*. These three cases were described in full detail, drawings of the morbid changes were shown, the literature relating to the subject was summarised, and the nature of the disease discussed. Dr. Williams believed it to be identical with the lupus seen on the skin and on other mucous membranes; and in this view, Dr. Matthews Duncan, one of those who subsequently spoke, concurred.

In the course of the recent discussion, at the Medical Society, on the cold-bath treatment of enteric fever, the President, Sir Joseph Fayrer, handed round, as bearing on the subject, two sketches—one of which is reproduced below—which had been sent to him by Surgeon-General Townsend, C.B. They represent a plan of putting young children to sleep, followed in many parts of the Himalayas. "Near almost every village," said Sir Joseph Fayrer, in explaining the sketches, "there are one or more small channels by which the water from the neighbouring spring is conducted to the cultivated plots of ground for the purpose of irrigation, and these channels are, in parts, formed of troughs, hollowed out of fir-trees. A piece of bark or matting is laid on the lower of two of these troughs, and on this the infant, swathed in a large mass of clothes, is so placed that the water from the upper trough falls on the vertex of the cranium, and, glancing off thence, runs away under the bark or matting without further wetting the child or its clothes; or, if the stream is full and copious, the child is placed on the side of the channel, and a portion of the stream directed on its head by a large leaf or piece of bark, another leaf or piece of bark being arranged on the other side of the head so as to catch the water and carry it away. Children, so placed, will lie asleep for hours, and the mothers leave them while they go about their daily occupation. The child's head and face are more muffled up than appears in the sketches, little more than the vertex of the cranium, on which the water falls, being left uncovered."

The bath treatment of enteric fever, which, if not absolutely originated, was at least brought into prominent notice for the first time, in Germany, has lately been the subject of discussion at the Medical Society of Leipsic. No overwhelming consensus of opinion was brought to light as to the universal value of the treatment, although its acceptance would appear to be general. Its action, however, is differently regarded by many German authorities. The view, that the high temperature is to be looked upon as the important aspect in the clinical features of a case, and that the beneficial effects of cold or tepid water are wrought by means of reduction of temperature alone, is by no means generally accepted. A condition of extreme depression, accompanied by all the signs and symptoms

generally grouped together under the name of the "typhoid state," is not absolutely dependent either for its causation or maintenance upon a very high temperature. But it is precisely in these cases that the beneficial effect of bathing is most marked, and especially when cold affusion to the head is added to the general immersion of the body. The semi-unconscious and wholly apathetic state of mind is replaced by complete consciousness, and often some sign of intelligence and interest, whilst the tendency to bed-sores and other evidences of circulatory stagnation is unquestionably diminished. It is evident that all these phenomena are but signs of an improved vaso-motor excitability; but opinions will probably remain, as they now are, divided, as to the precise manner in which this improvement takes place.

A PATENT of nobility has just been granted to Professor Frerichs, in Berlin. This recognition of the merits of one of the foremost clinical professors of the present day has been received with great satisfaction in Berlin, and there are doubtless very many of his friends and former students in this country and America who will gladly join with us in congratulations to Dr. von Frerichs on the well-merited distinction thus bestowed upon him. We regret to hear at the same time that Dr. Frerichs is at present unable, owing to illness, to deliver his clinical lectures; and that it is reported that after the celebration of his 25th year as Director of the University Medical Clinic by a jubilee on the 1st of April next, it is his intention, on account of his failing health, to retire from the post which he has filled with such conspicuous ability.

WE understand that arrangements have been made for the publication of a monthly periodical, dealing with Laryngology and its allied sciences, on a plan which will at once recommend itself not only to specialists but to the profession at large. Contributions to the literature of these subjects have of late years been freely admitted to the most prominent columns of all the leading medical journals, and the "original communications" which have failed on their merits to secure this more exalted form of publicity have gone to swell the pages, but not the intrinsic value, of various special journals. Thus all the work that has been hitherto done, lies hopelessly scattered through the periodical literature of many lands, and the so-called special journals are not representative of the better kind of study. It is now proposed, therefore, to remedy this state of affairs by the establishment of a periodical, whose chief end and object shall be *reporting*—to bring together, month by month, a careful and concise account of all the work that has been done in the meantime, in any part of the medical world, and to review in a thorough and temperate spirit any published works bearing on the subjects. The reviews will, in every case, be signed. The work being thus international, will be published in the language best known to the majority of laryngologists, viz., German. A guarantee for the thoroughly scientific spirit in which the work will be undertaken is given by the names of the intending contributors, who are united under the editorship of Dr. Felix Semon. The distinguished support which the project has already received in this country and upon the Continent augurs well for the future success of the *Internationales Centralblatt für Laryngologie, Rhinologie und verwandte Wissenschaften.*

THOSE who have attended Dr. Widerhofer's crowded clinic, at Vienna, will be glad to hear that he has just been unanimously chosen as Ordinary Professor of the Diseases of Children in the Vienna Medical Faculty. It is strange that one of his eminence, both as a practitioner and teacher, should not have been promoted before this from the extraordinary professorship, which he has held for seventeen years.

HIS Excellency Herr von Langenbeck has issued invitations, from his beautiful retreat at Wiesbaden, for the thirteenth meeting of the Congress of German Surgeons, to be held in Berlin from the 16th to the 19th April. By a resolution passed at the congress of last year, it was determined that all papers to be read at the meeting must be communicated to the secretaries by the end of January; but as at that date only three papers had arrived, the period for their reception was extended to the end of February. The third Congress for Internal Medicine is also to be held at Berlin from the 21st to the 24th April, under the presidency of Geheim-Ober-Medicinal-Rath von Frerichs.

THE death-rate of the 28 great towns fell last week from 21·1 to 20·3 per 1,000, while the London death-rate fell from 20·2 to 19·3, a lower figure than has been yet recorded this year. In London there was a marked fall in the zymotic deaths, from 208 to 179; while in the other 27 towns this class of deaths showed a slight rise, from 221 to 226. Compared with former years, the deaths from zymotic disease were 51, and the deaths from respiratory disease 162, below the corrected decennial average, and this though the mean temperature of the week was nearly 2° below the average. The deaths from small-pox during the week were higher than in any of the previous eight weeks of this year, but the epidemic does not appear to have spread in the way it threatened at the date of the last return. Only twenty new cases were admitted into the asylum hospitals, against 28 in each of the two previous weeks.

IN the eight large Scottish towns the death-rate rose last week by 0·6, instead of falling, as in the case of the English towns. The zymotic death-rate also experienced a rise of 0·3, and was 3·5 per 1,000 as compared with the English rate of 2·4. Diphtheria was, as usual, very fatal in the northern towns, causing seventeen deaths in the week, exactly the same number that it caused in 27 large English towns, with an aggregate population four times as large.

IN his report on the last quarter of 1883, Dr. Alfred Hill, the Medical Officer of Health for Birmingham, is in a position to show a sensible decrease in the mortality of his district from zymotic diseases. The death-rate from this cause fell from 3·1 and

3·2 in the fourth quarters of 1881 and 1882 respectively, to 2·8 in the quarter above referred to. Diarrhœa proved the most fatal of the zymotics, while singularly enough the deaths from whooping-cough—only 17 as compared with 91 in the similar quarter of 1882—were the lowest recorded in any quarter since these records were established. Birmingham would appear to share with the metropolis the difficulty of stamping out entirely the scourge of small-pox, and forty deaths were attributed to this cause, as compared with only two in the corresponding quarter of the previous year; the cases which came to Dr. Hill's knowledge, numbered 435, the per-centage of mortality being as low as 9·2 against 9·5 in the preceding three months.

Setting aside the effusion in *Blackwood*, which we noticed last week, the paper of most interest from a medical point of view, in the March magazines, is Dr. Tirard's thoughtful and readable article in the *National Review*, on out-patient work in children's hospitals. Dr. Tirard's main contention is that the physician will never be able to do his best for his little patients unless we can get the lowest orders to realise a few of the simplest conditions of health, and the most rudimentary facts of contagion. "So far as the work of our children's hospitals goes," Dr. Tirard writes, "every physician feels that his greatest labour is expended in giving advice, that he does far more good by this than by resting satisfied with attempting to counteract errors merely by the administration of cod-liver oil, &c." But from ignorance amongst the poor, the physician's advice is too often "set aside in deference to those of the neighbours, old dames replete with sage saws and ancient aphorisms, with hazy notions of symptoms and quaint superstitious charms for remedies." Dr. Tirard holds that the main remedy is to be found in teaching more hygiene and public health in our Board schools, but against such a proposal "doubtless a cry would be raised by the British ratepayer." Not only, unfortunately, by the British ratepayer! Some time ago, as our readers may remember, Dr. Allchin, who has also had a long experience of children's hospitals as well as of science teaching amongst the lower orders, maintained that it is useles to teach physiology in primary schools, and that the only way to get hospital patients to carry out instructions is by an emphatic "do this," on the part of the physician. To us Dr. Tirard's appears the more hopeful and the more reasonable contention.

The *Nineteenth Century* opens with a manifesto in its largest type, by the committee of a new "Society for the enforcement of sanitary laws and the improvement of Dwellings," of which Mr. James Knowles is secretary. The committee is strong but mixed, consisting of the Baroness Burdett-Coutts, Miss Octavia Hill, the Earls of Shaftesbury and Dunraven, Sir Richard Cross and Mr. Shaw-Lefevre, Mr. Samuel Morley and Mr. Burt, the Rev. S. A. Barnett, Mr. Arnold-Forster and the Secretary. The Society, the object of which is to improve the dwellings of the poor by enforcing the existing law, is a satire on our methods of local government. It is like having to form private committees of safety to help the police to deal with pickpockets. It is true that local authorities want looking after, but would it not be saving time to reorganise them at once? The same magazine contains one of Mr. Traill's delightful colloquies, entitled "The Brutes on their Master," in which he touches lightly, but not unkindly, on the subject of vivisection.

Macmillan contains a short but interesting note on the experiment of boarding-out London children amongst the cottagers of the New Forest. It has only been tried for two summers, but so far the results have been most satisfactory. In the *Atlantic Monthly*, besides a graceful set of verses by Dr. Wendell Holmes, there is a paper on the discovery of Peruvian bark, which is not entirely agreeable reading for a doctor. The faculty certainly does not come out well in the history of its relations to the drug. In the case of the Countess of Chinchon, the Court doctors, the surgeon-general of the army, and the chief surgeons of the Spanish ships of war at Callao, all appear to have opposed the administration of the Indian powder, then but little known, and their unwillingness to experiment upon their aristocratic patient may be amply justified. But the conduct of King Charles II.'s physicians, nearly a century and a half later, and of those of Frederick the Great, over two centuries later, is not so easily excused. The bark was introduced into notice in England by an apothecary, named Tudor, but the physicians would have nothing to do with it. Evelyn records in his diary that they "would not give it to the king at a time when in a dangerous ague it was the only thing that would cure him (out of envy because it had been brought into vogue by Mr. Tudor, an apothecary). . . . . Being asked why they would not prescribe it, Dr. Lower said it would spoil their practice, or some such expression." In the case of Frederick the Great, we are told that he bitterly reviled his physicians "that they would not give him the drug of which he had heard, nor cure him of the fever, having nothing better than Pyrmont water to offer for his relief." The sting is taken out of these recitals when we remember the change that has come over the profession, which no one now is likely to accuse of prejudice against new remedies.

In Dr. Alexander Wood, who died at Edinburgh on the 26th ultimo, another of the original members of the General Medical Council has passed over to join the majority of his colleagues. Dr. Wood was the son of an Edinburgh practitioner; he took his degree at the Edinburgh University, and entered practice at a comparatively early age. In 1844, he became lecturer on the practice of physic, at the Extra-Mural School, and held the post for ten years. In 1855, he was a candidate for the corresponding Chair in the University, but was beaten by Dr. Laycock. He closely associated himself with the Edinburgh College of Physicians, and when the Medical Council was instituted in 1858, was chosen by the College as its representative. He resigned this position in 1873, at about the same time that he gave up active practice. Dr. Wood also took a considerable share in the

management of the affairs of the Edinburgh University, and he acted as assessor during Mr. Gladstone's rectorship. His contributions to science were not remarkable. He had something to do with the introduction of chloroform by Sir James Simpson, and he contributed to the invention of the hypodermic syringe. But he will be remembered far more for his public, than for his scientific services.

The removal of the Medical School of Anderson's College, Glasgow, to the neighbourhood of the Western Infirmary, which has long been under consideration, is now in a fair way of being realised. There is a scheme for the amalgamation of Anderson's College with the College of Science and Arts, and other schools, to form a large Technical College, under the provisions of schemes framed by the Commissioners under the Educational Endowments Act. It has been prepared on the assumption that the Medical Faculty will be removed from Anderson's College. At a meeting of the managers with a deputation from the Medical Faculty of Anderson's College, the subject has been discussed, and the proposal made to build a suitable house in the West End of Glasgow for their Medical School. The professors have urged the claims of the Medical School, which ought to be generously dealt with at this juncture, inasmuch as it is the Medical School which has kept the College afloat for the last forty years, and has enabled it to hand over property and funds to the amount of 67,000*l.* to the new Technical College. There is also this to be urged upon the consideration of the managers and the Glasgow public: that as the name of the founder of the College, will henceforth be associated only with the Medical School, the memorial ought to be of such a character as to confer honour upon all parties concerned.

We learn that the annual dinner of the Irish Graduates' Association will be held at the Holborn Restaurant, on St. Patrick's Day (Monday, March 17th), Professor G. F. Yeo in the chair. Tickets and further information may be obtained from Dr. J. Thompson, 1, Matheson-road, West Kensington, W.

A deputation from the Royal College of Surgeons in Ireland waited on his Excellency the Lord Lieutenant, at Dublin Castle, on Monday, March 3rd, to present the resolutions adopted at the recent special meeting of the College, and urge the views therein expressed as to the provisions of "The Medical Act Amendment Bill," introduced by the Government last session, and again presented to the Upper House by Lord Carlingford, as Lord President of the Council. The deputation comprised Mr. W. I. Wheeler, President of the College; Dr. W. Colles, Secretary of the College; Dr. Edward Hamilton, ex-President; Dr. J. Stannus Hughes, Secretary of the Council; Dr. George H. Kidd, ex-President; Dr. Rawdon Macnamara, ex-President and Representative of the College on the General Medical Council; and Mr. John Kellock Barton, ex-President. His Excellency, in reply to the deputation, said he thought a great deal of unnecessary alarm had been created by the Bill, and he was quite certain the Government did not intend to bring to "uselessness" and "poverty," a body that had done such eminent service as the Royal College of Surgeons in Ireland; but Lord Carlingford would be most ready to take into account any representations made by the College on the subject of the Bill.

We have to chronicle the untimely fate of the latest Conjoint Examination Scheme for Ireland, which was "floated" some three months ago by the King and Queen's College of Physicians and the Royal College of Surgeons in Ireland. The collapse of this—probably the final—effort to establish a conjoint examination between the two colleges was brought about by the council of the College of Surgeons, who thought proper to append to the *ad interim* report of a joint committee of the colleges on the subject, the proposition—"That it is desirable that the Apothecaries' Society should be requested to co-operate in the Conjoint Scheme of Examinations." It is scarcely necessary to state that the College of Physicians regarded this resolution as distinctly outside the proposed scheme and altogether irregular.

In his fourteenth annual report on the "Health of Salford," during the year 1882, Dr. John Tatham, the Medical Officer of Health, commenting upon the means at his disposal for dealing with infectious diseases, remarks, that of the 5,000 cases of infectious sickness, which, in round numbers, probably occurred in his district during 1882, not more than one case in four was reported at his office; consequently the power which the Health Department possessed over the spread of diseases of this character, was proportionately limited. During the whole of the year under notice, 1,261 cases of the principal zymotic diseases were reported; the death register, however, records within the same period the deaths of 499 persons from these diseases. Unless, therefore, it is decided to accept the proportion of two deaths in every five attacks, as the average mortality to which infectious maladies give rise, the conclusion seems inevitable, that of the total number of sick cases that occur, the Salford Health Department receives information with respect to only a very small and inadequate proportion; and this, viewed from a preventive standpoint, discloses a state of things the reverse of satisfactory.

The rate of mortality due to the miasmatic class of diseases in Salford was, during 1882, equal to 2·7 per 1,000, as compared with 3·9, the mean of the annual rates in the preceding decennium. Dr. Tatham publishes a table which he has compiled from the quarterly returns of the Registrar-General, and by which he shows that throughout the country generally the incidence of infectious disease during the year 1882 was unusually light, a result due, he considers, to meteorological conditions of the nature of which we know little, but which seem to determine the prevalence of such diseases. He also claims for Salford a very fair position in the list, as regards its miasmatic rate, since this latter is lower than the average rate of the 28 great English towns, many of which enjoy natural advantages which Salford does not possess.

The question of the right of hospital doctors to make *post-mortem* examinations on their patients against the wishes of the friends, is one that is continually coming before us. The latest case of the kind occurred a few days ago at St. Vincent's Hospital, Dublin, where Dr. F. J. B. Quinlan made a *post-mortem* examination, contrary to the distinctly expressed wish of the patient's father, on the body of a young woman who had died from heart-disease under his care. It seems to us that in so doing Dr. Quinlan clearly placed himself in the wrong. We are unfortunately only too familiar with the unreasoning unreasonableness of the friends on similar occasions, but under such circumstances there is no help for it, and the interests of science must yield in the face of crass superstition or crasser obstinacy. We fail to understand, however, what ground the coroner had for holding an inquest. We regret to hear that civil proceedings are about to be instituted against Dr. Quinlan, whose demeanour at the inquest was honourable alike to himself and the profession.

That a great deal of mischief is done to children every year by overwork in schools, we should not think of denying, and the infliction of injury in this way is by no means confined to Board schools, or indeed to any one class of schools. But those who would not injure the cause they advocate, must be sure of their facts before raising a cry of overwork. This reflection naturally suggests itself in connection with a recent case at Cheltenham, where an inquest was held on the body of a little girl, who had died from tubercular meningitis induced in part, at any rate in the opinion of her medical attendants, by overwork at school. The evidence, however, in support of this was not conclusive, and the jury returned a simple verdict of death from inflammation of the brain.

The Cambridge Graduates' Club have every reason to congratulate themselves on the success of their *conversazione* on the last day of February. Besides a very good concert, there was plenty of entertainment provided in the shape of artistic collections and scientific novelties. The one which deservedly attracted most attention was the working model of a railway signal, invented by Mr. Stanley Currie, of Caius College, Cambridge, in which the signal was moved by an electro-magnet, a lamp being at the same time lighted to show that the apparatus was in proper working order. Professor Hughes's sonometer, exhibited by Mr. Dalby, had at all times throughout the evening its complement of admirers, many of whom learnt for the first time, that their hearing was not so acute with the left as with the right ear. Dr. Heneage Gibbes gave a demonstration of various micro-organisms, beautifully stained and mounted. The guests mustered in greater force than their hosts, there being, we believe, about 120 of the former to 50 of the latter. It is rumoured that the Oxford medical graduates are going to follow the example of the sister University, and found a club on the same lines. Should this rumour prove to be correct, it may be that some day we shall hear of an amalgamation between the two clubs.

The American Commission appointed to enquire into the trade in hog products, have reported "that hog cholera is not present in meat packed for human food, and in no event is the disease communicable to human beings. As to trichinosis the report is less conclusive, because less is known with certainity of the manner in which living trichinæ or their germs are transmitted. It is known, however, that the processes of packing, and the time which elapses between the slaughter of the animals, and their consumption abroad, so diminishes the vitality and propagative power of the trichinæ as to prevent their development in the human body. No single instance, based on competent scientific testimony can be adduced of trichinosis in Europe, arising from the use of American packed swine products. In every single case in Germany, it has been found that the disease was traceable to the consumption of freshly killed native hogs, and its virulence diminishes with the lapse of time between killing and consumption."

The number of artificial teeth manufactured in the United States is said to amount to ten millions per annum. There are twelve manufactories, but one of them, founded in 1864, makes half the number sold. The value of these teeth is a million dollars. The materials of which they are composed are felspar, kaolin, and rock-crystal.

The *New York Medical Journal* and the *New York Medical Record*, for February 16th, contain detailed reports of the discussion on the "Prevention and Treatment of Puerperal Fever," which has lately taken place at the New York Academy of Medicine, the addresses of Dr. Fordyce Barker and Dr. Gaillard Thomas being given in full. In the latter journal is also a long and able communication from Dr. Simon Baruch, on "Objectionable Features of certain Methods of Prophylaxis against Puerperal Fever," a paper which at the present time, when there seems some danger of over-interference with normal processes, is very opportune.

Dr. Magnan, in a paper recently read at the Paris Biological Society, expounded the reasons which had led him to admit a peculiar form (or as he calls it, an episodic syndromus) of hereditary insanity, characterised by true anti-vivisectionist delirium, which seizes hold of certain sensitive and ill-balanced minds. Side by side with these anti-vivisectionists he places a particular species of vegetarians, who embrace exclusively vegetable diet, not as a measure of hygiene, but solely in order to avoid the slaughter of animals. The numerous facts which he analyses, "demonstrate once more how various are the colours under which hereditary insanity may manifest itself." Among these degenerate beings everything in fact becomes a cause of delirium, and thanks to this powerful predisposition, it is not necessary for its subjects to pass through the slow and progressive stages of development, which those who are the subjects of common insanity methodically traverse.

At a recent meeting of the Parisian *Société Médicale des Hôpitaux*, Dr. Martineau again brought forward

his case of successful inoculation of syphilis on a monkey. Now, eleven months after the inoculation, the animal is suffering from a "papulo-erosive" eruption on the buccal and pharyngeal mucous membranes; and further from epileptiform seizures. The syphilis, therefore, continues to develop in a normal manner. All the lesions hitherto observed have passed away without any form of treatment being adopted. M. Guyot and M. Féréal doubted whether the epilepsy could be considered as due to the syphilis, especially as the monkey is essentially of a nervous temperament, to which argument M. Martineau replied that previously this monkey had not exhibited either signs of epilepsy or other nervous phenomena. There would manifestly be a difference between immediate and remote epilepsy; in the present instance several months had passed since the inoculation was practised.

Dr. Clifford Allbutt begins his course of Gulstonian Lectures at the Royal College of Physicians, this (Friday) afternoon. He has chosen for his subject one which is very lightly passed over in the current text-books, viz., visceral neuroses, and he will devote his attention mainly to the neuroses of the abdominal, as distinguished from the thoracic and pelvic viscera. We may venture to foretell that Dr. Allbutt's lectures will be worthy of the great reputation he has won as an acute observer, clear thinker, and picturesque writer—Dr. Allbutt more nearly approaches in gifts to Dr. Wendell Holmes than any other medical writer of our time—and we may also predict that his remarks will cause some fluttering in certain dovecotes.

MEDICAL EDUCATION IN LONDON.

The conditions under which medicine is taught in the metropolis ought to engage the attention of all minds which are not content to live in the present, or to dwell upon the past. The subject is rapidly coming to the front; it is emerging out of the realms of *doctrinaire* discussion, into that of practical politics, and the passing of the Medical Act would in all probability at once bring us face to face with it. In spite of the immense advance in its organisation, in spite of the increase in the number of teachers, and the large sums that have been spent at almost every hospital in improving the appliances for teaching, there is not the slightest doubt that the education of medical students in London falls very far short of an ideal system. There is a reckless waste of effort and material, and an utter want of proportion between the attention paid to primary, and that paid to advanced subjects. The requirements of the primary examinations have forced upon us an almost universal system of private coaching, ruinous alike to the student and the teacher. It is a system which robs anatomy, physiology, and other primary subjects of whatever value they have as a means of culture, which converts the student into a schoolboy, and his teacher into a pedagogue. On the other hand, the requirements of the later examinations are so limited in scope, that a student may be sent out into the world to try his skill upon it, who not only is entirely ignorant of all special divisions of practice—such as insanity, diseases of the ear, throat, eye, and skin, and the administration of anæsthetics—but who has no living grasp of medicine, surgery, diet, nursing, or the general care of the sick. By dint of hard and systematised work on the part of their many teachers, the students are successfully forced through their examinations; but in the effort we sacrifice all the higher teaching of medicine, and the student, who has time and mind for it, finds that there is no place for him in our system, but that he must move on to make room for the ever-advancing phalanx of pass-men.

It is impossible nowadays to close one's eyes to the fact that London, as a centre of medical training, has powerful rivals, and she will have in the future to make great efforts to outstrip them. Considering the natural advantages which London possesses, the overwhelming mass of material, the crowd of able teachers, and the vigour of its scientific interest and enthusiasm, her supremacy as a medical *alma mater* ought not to stand in question for a moment. She ought to be able to rejoice at the success of her great rival in the North, and watch, with friendly interest, the local medical schools springing up into activity in the provinces, instead of viewing their advance with dread, as she does. But with all her advantages, London is so handicapped in the race, as compared with Edinburgh, Cambridge, and Manchester, that this dread of their rivalry in the future is in the highest degree reasonable. There are three difficulties with which London has to contend as a medical palæstra. First, the multiplicity of centres of primary medical instruction, which occasions a ruinous waste of both teaching effort and material. On this point we have sufficiently dwelt in previous articles. Secondly, the deficient organisation of the means for clinical teaching; and, thirdly, the inability to confer a medical degree upon more than an infinitesimal proportion of her students. In nothing has the want of a strong central authority been more felt than in the way in which small special hospitals have been allowed to spring up in all parts of the metropolis, with the result of drawing away from the schools of medicine, and so rendering useless for clinical teaching, a large and most valuable mass of material. This has been due in great measure to the neglect of the large hospitals to realise in the past the great importance which the specialties were destined to assume in medical practice. But it has also been due to a want of power, or of inclination, on the part of the Government to control private effort with a view to public benefit. Any pushing doctor, backed by a few wealthy friends, has been allowed to start a special hospital, whereas, if we had had a strong Minister of Education, no such institutions would have been allowed to come into existence, unless they could prove that they were able and adapted to provide for the teaching of students as well as for the treatment of the sick. We will say nothing now of the questionable devices to which many such hospitals are reduced in order to avoid bankruptcy. But if the special hospitals are to be of any use as educational institutions, it is absolutely necessary that they should be affiliated to, and in their teaching capacity governed by, the larger general hospitals. They can never be anything but a drag on us, till some such centralising scheme is introduced.

The medical degree difficulty, though we should place it last in importance, is likely to come on first for discussion. The "title of doctor" question is on the point of being emancipated from the stage of small print; it is passing, in compositor's language, from "nonpareil" into "bourgeois." Hitherto it has been associated with a sentimental grievance—it has been a country practitioner's question. Henceforward it will become a matter of practical importance—a matter for senates and councils, rather than for anonymous letter writers. London teachers are constantly complaining that some of their most promising students, after making a fruitless trial or two at Burlington Gardens, go away in disgust to other less strict Universities, where they can achieve a right to the title of doctor, without running the gauntlet of the many severe tests that the University of London imposes. The teacher who finds his pupils and their fees thus attracted away from him when he knows that, as far as teaching is concerned, he can give a good account of every rival, deserves the fullest sympathy. But it is hardly to be expected that the senate of the London University should consent to lower its standard, and place its medical degrees on a footing entirely different from its degrees in other faculties, should consent further to destroy the beneficial influence which its requirements have undoubtedly had upon the higher medical teaching, in order to keep the fees of students for hospitals in which it has no direct interest. That some modification in the earlier examinations is advisable may be readily admitted; but we believe the mass of London graduates throughout the country would, apart from all regard for vested interests, strenuously protest against a cheapening of the London M.B. or M.D. We hold that a medical degree ought to imply some special culture, some training in general science or philosophy beyond the rough knowledge of his profession, which the ordinary practitioner possesses; something even beyond the smattering of Latin, French, or German, which the College of Physicians requires of its members. A man may be a good practitioner of medicine without being a learned or cultured man, for the medical training is not necessarily in itself a liberal education, or one which brings with it a broad and philosophic tone of thought. To give the title of M.D. simply for a book-knowledge of anatomy and physiology, and average skill in bedside work, would be to rob it of all its best associations, and to make it comparatively worthless.

If then the London teachers are to compete with their rivals in the provinces, it must probably be by means of a better organisation of their unrivalled material. London has far and away better teachers than any other medical school in the country, and it is many times richer in material. But at present both are wasted. If the latter were properly focussed and utilised, and if the former were allowed more open competition, and the best of them freed from the hack-work of passing men through examinations, London could offer advantages to the student such as he could obtain nowhere else in the world. We should like to see London made, as it ought to be, the centre of the higher medical teaching of all the English-speaking races. We should like to see men coming from all parts of the country and the colonies, with their examinations passed, to follow in the train of the great clinical teachers that we have amongst us. We should like to see a central institute, which for a single fee could throw open all the clinical teaching of the metropolis to the student, so that whether he were drawn to medicine at Guy's, or surgery at St. Bartholomew's, or Listerism at King's College, or eye-surgery at Moorfields, he should be able to feel that he had a right there and was no alien. Such a system would not interfere with the teaching of our own students, it would incite both pupils and teachers to rivalry, and London would for the first time become, what it has every right to be, the *alma mater* of the medical world.

THE SCHOOLBOY AT SCHOOL.

The present is an era remarkable for attempts at union and co-operation in all directions, and amongst all sorts and conditions of men. The latest effort of this kind is one to which we would give a cordial welcome. The proposal to establish an Association of the Medical Officers of Schools, should cover a wide extent of valuable and hitherto almost unwrought ground; and, if effectually carried out, is capable of achieving results of which it would be difficult to over-estimate the prospective value and importance. The fact that the idea is born not a day too soon is rather an argument in its favour, and, indeed, augurs well for its success Too often in the world's history great discoveries and movements of undoubted intrinsic merit have been doomed to failure, simply because the public was not yet ripe for their reception and appreciation. Now, however, that education is so general, and especially now that educational methods and abuses occupy so considerable a share of general interest and attention, there is good reason to hope for that concurrent recognition from the outside public, for lack of which many a similar scheme has failed of attaining its full meed of usefulness. The practical value of such a body as that which it is now intended, we understand, to constitute, must, after all, largely depend upon the extent to which its conclusions and suggestions can act through and with the support of public opinion; and it is an immense advantage when, as in this instance, public opinion has itself been educated up to the point of receptive interest.

There is yet another reason for congratulation, and one which does not lie so immediately upon the surface. While people are roused by allegations of an epidemic of overwork in Board schools, and by a prognosis of national myopia, while their sympathies are harrowed by reports of the break-down of pupil-teachers and the suicides of sensitive scholars in National and Elementary schools, there seems to be some risk of overlooking the dangers, not less real or less painful of their kind, which attend the members of our public and larger private schools. That general attention has not hitherto been drawn in this direction may be due, in some measure at least, to the fact that the life and trials of the public-schoolboy do not ordinarily come within the ken of the vigilant district-visitor, or afford a theme of discourse to an energetic School-Board candidate; while it is also too generally assumed

that the children of the upper classes are, by virtue of their social position, beyond the incidence of those special causes which are known to be operative in the ranks below them. The idea is a fallacious and a misleading one: fallacious, because it ignores the universality of that high pressure and goading competition to which most evils of the modern educational system are attributable; misleading, because it implies that there are no perils attendant on the system of instruction pursued in public and in high-class private schools. The facts are quite otherwise. If intellect-driving is an irksome novelty to children recruited from slums and gutters, its effects are as evil, and are probably more keenly appreciated, amongst the children of the upper and middle classes. The conscientious son of a professional man who has a position to maintain with a large family and a limited and, perhaps, precarious income, will acutely realise the necessity for early securing a good start in life for the sake of his parents, and of his brothers and sisters, no less than for his own. By both friends and relatives he is continuously urged to make the most of his opportunities, and the precept is enforced by reference to examples of brilliant success amongst his fellows; while he is given to understand that he is expected to achieve results proportionate to the special advantages which are supposed to be attached to the favourable circumstances of his birth and social position. And thus, while an extra turn is given to the educational screw, the additional burden of personal worry is brought to bear upon a mind which is, not rarely, unduly sensitive. Moreover, the conditions under which such boys have to work are not by any means so generally favourable as most people are willing to believe. Most fathers will admit that now-a-days their sons are expected to master subjects of a variety, a nature, and an extent to which, in their own boyhood, they were almost strangers. A generation or two since, moreover, when the average standard of school work was considerably lower than is the case at present, the brilliant and clever worker came to the front *proprio motu* — because he could, from sheer natural and spontaneous ability outpace the crowd, and not because he was forced by a combination of all possible *stimuli* into a precocious and unnatural development. Now the tendency is rather to work all intellects up towards the same standard, to use the conspicuous successes of the few as incentives to further efforts on the part of the less gifted majority, and to fasten upon all the haunting worry of continuous competition. It may well be doubted whether, had he been exposed to influences such as these, Newton would, on the one hand, have been regarded almost as a dunce up to the age of eighteen; or, on the other, would have developed into that intellectual giant which the world recognised in his ripened manhood. The forced acorn grows rapidly into a tree, sappy as the willow, but it makes no heart-wood, and rapidly decays; and no system of cultivation will convert a poplar into a yew.

There is yet another point connected with this aspect of the question. Whilst, in the course of the present generation, the standard of average education has been so markedly raised, and the amount of work to be got out of, and of facts to be got into, each boy has been proportionately increased, the arrangements for feeding the body have in the larger and older schools undergone little if any modification. The breakfast, dinner, and tea actually provided in our best known public schools—however well they may have sufficed for the necessities of the easily worked scholar of some generations since—are now notoriously inadequate for the requirements of his modern representative. The hours of work are longer, bodily exercise is carried to an extreme, and at the same time the mental and intellectual faculties are being worked at the highest pressure obtainable, upon a school-fare which would barely suffice to make good the merely physical waste and repair of the growing lad of sixteen or seventeen. So unquestioned is this fact, that in these schools there obtains a regular system whereby, by special arrangement with his parents, each boy is at liberty to supplement the actual school provision with additional food up to a stipulated value. The result is, that, as the selection of this *addendum cibo* is left to a youth whose appetite is too often both balked and jaded by the combined paucity and monotony of the food regularly provided, he invests in the appetising sausage, or in some tinned or preserved meat, rather than in the chop or beefsteak or egg which would stand him in so much better stead; and probably no one whose experience has not lain amongst the juvenile consumers of such viands can fully appreciate the mischief which may be fairly laid to the charge of tinned meats and sausages. Our statements are quite within the mark, and as the subject is one of real and far-reaching importance, we may probably recur to it hereafter.

The younger schools, which have been fortunate in starting comparatively unhampered by tradition and by that strong topical conservatism to which the English schoolboy is so early wedded, are, as a rule, less open to reproach in such matters. But in all cases, the question of food and feeding; of exercise — its character, its amount, and its relation to meal-times; of school punishments; of lighting, heating, drainage, &c., are matters in which there may be noted a far greater variation of management and method than can be necessitated merely by the inherent variability of the genus *puer;* and these, therefore, are subjects which may fairly be considered worthy of discussion and adjustment. Leaving hygiene for more strictly medical questions, it would seem that the proposed Association might gather and elaborate most important information on the subject of the commoner epidemic diseases. The school-age is pre-eminently that during which, for instance, the contagious exanthemata are wont to be developed. The important material and observation which now so largely run to waste, could thus be collected and compared. And it is not easy to set a limit to the results which might be achieved by the careful comparison of a large number of full and accurate returns—each the work of a skilled observer engaged in noting the sequence of events in a large number of individuals who are drawn from practically the same class in life, and who live under practically identical conditions.

Although the remarks hitherto made have referred exclusively to boys' schools, it is not thence to be

inferred that there is no room for improvement in the hygienic and medical management of those establishments which are devoted to the education of the opposite sex; or that the material which is there available would not amply repay such record and observation as comes legitimately within the province of the medical attendant. But, in an age in which the equality of the sexes is preached from the house-tops, we may fairly expect that anything which is recommended or condemned in the school system to which boys are subjected, would come to be regarded with equal praise or blame in the case of girls, and would be made the basis of remedial action equally prompt and energetic in both cases.

The subject, of course, is not by any means exhausted; nor is it implied that the points to which we have drawn attention should be investigated just in the order in which we have alluded to them. The medical officers of schools should know their own work best, and should be able to judge to what quarter their efforts can be directed with the greatest advantage, and with the probability of attaining the most practical results. We have written rather with the object of rousing and stimulating that general interest in the subject without which, as has been already pointed out, no movement—whatever its origin or its object—can hope to secure real and permanent success.

CLINICAL PAPERS.

VII.—Chronic Tonsillitis and Tonsillotomy.

Chronic enlargement of the tonsils in young children is so common a condition in this country, as to deserve a little more attention than is usually paid to it in the routine instruction of the medical schools. Students generally leave their hospital studies imbued with one of two guiding principles on the subject of its treatment. Either they agree to leave the tonsils alone in all cases, or they decide to cut them out. The disciples of the latter school are probably the more numerous. The operation of tonsillotomy is, when skilfully performed, as gratifying to the feelings of the operator as it is, when the pain has subsided, to those of the patient, and hence it is not to be wondered at if the self-satisfaction thus induced sometimes leads the surgeon, confident of success, to operate, without further question of the relative advantages to be gained by the patient. Is tonsillotomy a complete cure for enlarged tonsils? The experience of those patients, probably well known to all hospital physicians and surgeons, who have had their tonsils taken out "again and again," would return a negative answer. If, by the ordinary operation, we could ensure the complete enucleation of the whole gland, there would probably be no return of the overgrowth; but the simplicity of the tonsillotome, which enables the operation to be all but momentary in duration, carries with it the disadvantage of almost invariably incomplete removal, which was effectually avoided by the ancient procedure of enucleation by the finger nail. It is to the subject of recurrent or fluctuating tonsillitis that attention is directed in the present paper.

Without entering into the larger question of the ætiology of the disease, it may be taken for granted that the tendency to suffer from hypertrophy of the tonsils is peculiar to certain individuals, and usually those of a strumous type. In some cases, but by no means in all, there exists a concurrent tendency to hypertrophy of other lymphatic glands. That very considerable hypertrophy of the tonsils may exist, wholly unsuspected, either by the patients or their friends, is also a familiar fact. But it is not until they come under close observation that the discovery can be made that these overgrown glands are liable to frequent fluctuation in their size, and hence in the symptoms which they produce. Intending operators have frequently been astonished, on appointing a convenient day for tonsillotomy, to find that the urgent need for immediate removal, which they have been impressing on the minds of parents and friends, has, in the meantime, become considerably lessened by the independent conduct of the tonsils themselves. What then is the cause of this occasional fluctuation, and this frequent regrowth after removal? The answer may be found by examining the minute anatomy of the tonsil. Being entirely composed of lymphatic and adenoid tissue, it is, like all other similar tissues in the body, liable both to tumefaction and to hypertrophy. More liable, indeed, than most of the deep seated lymphatic structures, from its more exposed position, to become acutely inflamed in response to the action of direct irritants. But the chronic and fluctuating enlargement must be regarded in the light of a diathetic condition, and may thus be classed with the chronic enlargement, sometimes coexistent with it, of the cervical glands. In dealing with it we must look to something more than the local changes as seen through the mouth. The symptoms which it induces, or rather the symptoms which accompany it, are so various that it is often impossible to connect the effect with the supposed cause. The characteristic changes in the face, the noisy respiration during sleep, and the occasional deafness are easily explained, but the very marked depression of spirits, the abdominal pain and frequently capricious appetite are not quite such obvious results of the pharyngeal obstruction, nor is the explanation rendered clearer by the complete relief sometimes afforded to these general symptoms, whilst the local trouble remains unchanged. In such cases the removal of the overgrown tonsils is as little necessary as would be the removal of the enlarged lymphatic glands in the neck. So long as the two chief functions of respiration and deglutition can be efficiently carried on, the greater or less tumefaction of the tonsils is a matter of indifference, and in a very large proportion of cases these conditions are present.

The tendency of tonsillar hypertrophy to diminish, even to atrophy, as age advances, should be borne in mind, side by side with the fact that where the tendency to hypertrophy exists, it is sure to manifest itself even after an almost absolute ablation of the gland. The treatment of cases of ill-health accompanied by enlarged tonsils should, therefore, always be aimed first towards the relief of the general, and not of the local, symptoms, and in many cases it will be found that iron and cod-liver oil will do their work as well before tonsillotomy as after it. Only when the local obstruction is giving

rise to really severe or dangerous symptoms is it necessary to have recourse to immediate excision. Not unfrequently in such cases there are also present abundant adenoid growths in the vault of the pharynx, and under these circumstances no advantage can be gained by delay in operating. But in the ordinary cases of moderate enlargement in which the concomitant symptoms are as characteristic of a simple strumous cachexia as of any special form of glandular hypertrophy, the hasty resort to operative measures is to be deprecated. The fallacy of the rule *post hoc ergo propter hoc* is nowhere more clearly illustrated than in these cases, where hypertrophied tonsils are found guilty, condemned and executed for crimes of which they are themselves the victims, only to rise again, as feebly hypertrophied stumps, in judgment upon the mistaken zeal of their executioner.

B.

REVIEWS AND NOTICES OF BOOKS.

RIVINGTON ON RUPTURE OF THE BLADDER.[1]

Rupture of the bladder, although not a common accident, occurs with sufficient frequency to make it possible that any medical man may sometime or other find himself compelled to decide whether this injury has occurred or not; and if he is satisfied that it has happened, he may still further be obliged to determine the best plan of treatment to adopt. The teaching of ordinary text-books has probably left his mind without any very definite ideas on the subject, and if he is a student of current literature, he will very likely recollect that one surgeon has opened the bladder by lateral cystotomy, or that another has opened the abdominal cavity and stitched up the vesical rent, with no very good results. The profession, therefore, owes its thanks to any one who will undertake the reading and thought necessary to concentrate our knowledge on such a subject. Mr. Rivington has done this, and has produced a volume which every practitioner should read, and which surgeons will do well, not only to read, but to put upon their shelves. The author avoids, as foreign to his subject, gunshot injuries and penetrating wounds of the bladder, and he leaves unnoticed cases, where bone, and possibly surgical instruments, have found their way into the bladder by a process of ulceration. He only considers rupture of the bladder when produced by violence from without, or by pressure from within. In the first place, he clearly divides the injury into two kinds, the intra-peritonæal and the extra-peritonæal; the former being rupture where the peritonæum forms part of the vesical wall, and where extravasation of urine must necessarily take place into the peritonæal cavity; and the latter where the rupture is through the wall where uncovered with peritonæum. For practical purposes it is unnecessary to refer particularly to partial ruptures or to sub-peritonæal ruptures which, of course, are sub-divisions only of the second great division, *i.e.*, extra-peritonæal. Both the great divisions may be either idiopathic or traumatic, and the traumatic rupture may or may not be associated with fracture of the pelvis. Diagnosis is carefully discussed, and it is shown that before the existence of traumatic rupture is determined upon, it must be absolutely proved that the bladder was full at the time of the accident, and that sufficient force to produce rupture has been applied to the hypogastric region. It is also explained that all the typical signs of vesical rupture may frequently be partially absent, and occasionally nearly entirely so, such as, a feeling that something has given way, pain, shock, want of power to micturate, removal from the bladder with the catheter of blood only of a small quantity of bloody urine, so that often diagnosis is not an easy matter. In extra-peritonæal ruptures doubt will soon be removed by the occurrence of extravasation of urine, but in intra-peritonæal ruptures the author considers the best local test is the possibility of passing the point of a long silver catheter through the rent into the peritonæal cavity, finding the end of the catheter freely movable, and drawing off a large quantity of urine after the catheter has apparently passed beyond the bladder. It is here that, perhaps, some surgical readers will not find themselves quite in accord with Mr. Rivington. They may consider this manipulation safe enough in the hands of a skilful surgeon, but highly dangerous in ordinary hands, especially if no means have been employed to cleanse the interior of the catheter, particularly the portion beyond its eye; whereas no harm can be done by introducing a soft catheter fairly into the bladder, and most important information can be gathered from the injection of warm carbolised water through this inlying catheter, first of all noting the character of the urine, if any is drawn off. If the catheter is fairly in the bladder, and if its interior is not blocked up, as much injected fluid will be returned on removing the syringe, as was put in; if the bladder is not ruptured. If the injection is not returned, a finger in the bowel, with suprapubic pressure and percussion, will determine whether the bladder is empty or not. If the bladder appears empty, and the catheter is found not blocked up by clot, and especially if, as in Mr. Christopher Heath's celebrated case, the patient feels the warm injection in his groins, the case will certainly be one of intra-peritonæal rupture, and the process of diagnosis will have inflicted no injury upon the patient. Mr. Rivington does not refer to examination *per rectum* in these cases in favourable terms, although practical surgeons have relied very much upon it as an aid to diagnosis.

Supposing, then, that the surgeon is convinced that there is an opening in the bladder wall, and that urine and possibly injected fluid have escaped into the peritonæal cavity, what is he to do? Mr. Rivington has taken great pains to answer this question as fully as the present state of our knowledge permits. He has collected and digested, it appears to us, all the literature of the subject, not excepting the most recent published cases. His consideration of the eight well-known cases of reported recovery, after intra-peritonæal rupture is most interesting; he approaches them all in the true scientific spirit, and takes nothing on trust, with the result that he is only willing to accept one, that of

[1] Rupture of the Urinary Bladder, by Walter Rivington, F.R.C.S. J. & A. Churchill, London, 1884.

Dr. Walter, and he is not quite sure even of that. The cases of Dr. Thorp and Mr. Chaldecott, which have, perhaps, had more influence in the formation of surgical opinion than others, are dismissed as unworthy of credence. But, as the author remarks, if all these eight cases could be accepted, surgeons would still be in doubt as to treatment, for in all different plans were carried out. The subject is one of much importance, as was shown by the interest taken by surgeons in Mr. Christopher Heath's somewhat recent paper before the Royal Medical and Chirurgical Society. In the case, which formed the subject of his paper, Mr. Heath adopted Mr. Willett's plan of opening the abdomen, removing the extravasated urine, and stitching up the rent in the bladder. The cases of Mr. Willett and Mr. Heath both ended fatally, but there were sufficiently favourable signs in each, to induce surgeons to give the plan further trial. Mr. Rivington is satisfied that the first thing to do is to open the abdomen, and remove the extravasated urine and blood; he also thinks that a free perinæal opening for the draining of the bladder is desirable, but he does not say whether he prefers a median or a lateral cystotomy, or only an external perinæal urethrotomy. He considers the question of stitching up the bladder as still *sub judice*. If a surgeon can fully accept Dr. Walter's case, he may be tempted to leave the wound alone, and simply clear out the peritonæal cavity, and drain the bladder; for it is quite comprehensible that a bladder being ruptured when full, the wound in it, when the bladder is collapsed and kept empty, may be oblique and soon closed by the efforts of nature. The question of perinæal opening is also still an undecided one, with ordinary care the bladder may be thoroughly drained, if a catheter is tied in and tubing attached, and many of these patients are not in a state to be exposed to the risks of operative interference, unless absolutely necessary.

We have confined ourselves in this notice to a few points which particularly concern the practical surgeon, but the work is full of matter interesting to all, and it is not often that we have read a book of the kind, from cover to cover, with so much pleasure and profit.

ABSTRACTS AND EXTRACTS.

M. PASTEUR ON RABIES.

In a communication read at the meeting of the Académie de Médecine, Feb. 26, M. Pasteur gave an account of the results of the researches which he has been pursuing, concerning rabies, since his former communication in 1882. They are based upon a large number of experiments made on various animals, by inoculating the surface of the brain with rabid virus, or by introducing this into the circulation. The following are the chief conclusions to be derived from these experiments. 1. The spinal cord becomes affected by the virus of rabies before the medulla oblongata. 2. The virus has its seat not only in the encephalon and the spinal cord, but in the whole nervous system from the centre to the periphery, a fact which explains the nervous excitement manifested in so many instances, and as well as the strange symptom ærophobia in men often exhibited. The virulence of the saliva and of the salivary glands has been demonstrated on dogs rendered rabid by intra-cranial or intra-venous inoculations, as well as in those attacked by so-called spontaneous rabies. 3. The virus may be possessed, with all its virulence, in the encephalon and cord during several weeks, when putrefaction of the bodies is prevented by a low temperature. The virus also enclosed in hermetically sealed tubes may be preserved for three or four weeks at a summer temperature. 4. The virus of rabies may exist in the cerebro-spinal fluid, but its presence there is not constant. 5. Although the brain in rabies is distinguishable from the healthy brain by the greater number and delicacy of the molecular granulations, no microbe has as yet been detected. 6. We know, that usually when a bitten dog becomes mad, he becomes furious with a propensity to bite, and a peculier bark; but in these experiments, when the virus was passed into a vein or the subcutaneous tissue, the paralytic form of the disease was ordinarily produced without fury or barking, while when intra-cranial inoculation was resorted to, furious rabies was the usual result. This latter form was only producible by intra-venous or hypodermic injection, when very small quantities of virus were employed. The smaller the amount of virus employed for these injections, the more easily was furious rabies produced. On the other hand, the inoculations of small quantities of virus greatly prolonged the duration of the incubation; and if the dilution be pushed beyond a certain limit, which is not very high, the inoculation produces no effect. But while these small quantities do not induce rabies, the animal is still susceptible to the infection in subsequent inoculations, that is, the first inoculation confers no immunity. 7. As had been already observed in the dog, so in the rabbit, there may be a remission of the early symptoms of rabies, with a recurrence of the disease some time afterwards. This occurrence is, however, very rare both in the dog and the rabbit, while in the fowl it frequently takes place. 8. Numerous experiments have been made with regard to the alleged attenuation of the virus of rabies by the action of cold; but the results have been entirely negative. 9. The certainty of inoculation by intra-venous injection of the virus, proves that the hypothesis of its passage from the periphery to the nerve centres by means of the nerves, cannot be regarded as its sole channel of propagation, and that in most cases its absorption takes place through the circulation. 10. The passage of the virus through different species of animals, permits of a more or less considerable modification of its virulence. Rabbits, guinea-pigs, fowls, monkeys, all take rabies; and when, by successive inoculation, the virus attains a kind of fixity proper to each genus, the different viruses vary greatly in strength, and differ appreciably in this respect from the canine virus, the virulence of which has become fixed by its numerous passages from dog to dog, by means of bites, from time immemorial. M. Pasteur is no believer in spontaneous rabies. At the present time we are in possession of a virus which imparts rabies to a rabbit in seven or eight days, with such constancy, that we are able to assign to within some hours, so to say, the duration of the incubation, measured by the change of temperature, or by the first manifestation of the symptoms. We also possess a virus which will give rabies to the guinea-pig in five or six days, with not less constancy in the duration of the incubation. As the nearest approach to man, M. Pasteur is at present engaged in a series of experiments upon the passage of rabies from monkey to monkey 11. In a former communication, M. Pasteur stated that he had some dogs in his laboratory which had proved insusceptible to all modes of inoculation; but at that time he was unable to state whether they were naturally insusceptible to the poison, or had been rendered so by some of the circumstances to which they had been submitted. He now believes that they were not constitutionally insusceptible, for he has now discovered a practical method of rendering the dog insusceptible to rabies at will. Considering, however, that the inoculation of rabies may be very prolonged, and that this may always throw doubts on the proofs adduced, he asks the Academy to give credit for a time to his assertion, that this insusceptible condition may be produced by a system of inoculation. He possesses at the present time 23 dogs which have been subjected to virulent inoculations without danger. "To thus render the dogs insusceptible to rabies would be not only a solution of the question of prophylaxis of this affection in the dog, but also in man, as man never contracts rabies but as the result

of a bite, the virus from which proceeds directly or indirectly from the dog. May not human medicine profit by the long duration of the period of incubation of rabies, and endeavour to establish in this interval of time, before the appearance of the first hydrophobic symptoms, a condition of insusceptibility on the part of the bitten persons? But before such a hope as this can be realised, a long path has yet to be traversed."

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MARCH 4TH, 1884.

J. WHITAKER HULKE, ESQ., F.R.S., President, in the Chair.

Fractures of the Sternum and First Costal Cartilage.

MR. ARBUTHNOT LANE read a paper on one way in which the sternum may be fractured. After referring to the views of M. Maisonneuve and Mr. Rivington, Mr. Lane stated that the first cartilage was one inch and a half deep at its attachment to the manubrium, while the second cartilage was only five-eighths of an inch, so that when one cartilage was depressed by the clavicle, it tended to cause the manubrium to rotate around an antero-posterior axis, and also affected the opposite cartilage. If the pressure exerted were very great, one or both first costal cartilages might be broken, together with the sternum, without there being any displacement of fragments. Or only one cartilage might be broken. If the cartilages were very elastic, and the sternum rigid, it alone might yield, as in an experiment he had made on the dead body. In this case, the manubrium was ossified to the gladiolus. A heavy blow was struck on the outer extremity of the clavicle, a fracture of the sternum at a point which corresponded to the junction of the first and second pieces resulted, the fragments not having been displaced. In other cases, the ligaments binding down the inner extremity of the clavicle might give way, and dislocation upwards ensue. As exemplifying this last result, he showed a specimen from the museum of Guy's Hospital, in which the inner end of the clavicle had been dislocated upwards, and the ossified first costal cartilage was fractured on the same side. Its line of fracture was irregular, and not vertical, as in fracture of the ordinary elastic cartilage. The sternum was not fractured. Mr. Lane showed a specimen similar to one which he had shown at the Society last year. The first cartilages and sternum had sustained the same fractures, no other bones in the body showing any sign of fracture. A case recorded by Dr. Bennett, *Dublin Quarterly Journal*, served also to illustrate his view. A heavy weight fell on a man, fracturing many bones. That which had fallen on the clavicles had fractured both first cartilages and the sternum at the junction of the first and second pieces. He believed that fracture of the sternum or cartilages, or of both, were not so very uncommon as the scanty literature on the subject would suggest; also that M. Maisonneuve had no clear idea of how the clavicle transmitted force to the sternum, which it did only indirectly by pressure on the first rib and cartilage. M. Maisonneuve apparently arrived at this conclusion by observing the frequent concomitance of fracture of the scapula and clavicle with that of the sternum. The sternum and cartilages, when fractured by this means, would present very little sign during life, nor at a period long after the injury, owing to the fractures remaining in apposition. It was very difficult to decide, in many ossified first cartilages, whether they had been fractured or not, as they frequently presented a very irregular outline, owing to abundant deposit of new bone, which might either be the result of fracture, or thrown up to support the joint formed in this situation.

MR. ROGER WILLIAMS thought that Mr. Lane had not laid enough stress upon the part played by the ligaments attached to the clavicle, especially the rhomboid, trapezoid, and conoid ligaments, in transmitting the shock of a blow.

MR. LOCKWOOD had examined the specimen, and doubted whether there was really any fracture of the sternum. The evidence of fracture of the costal cartilages was only slight, there was some heaping up of cartilage and bone, but if there was a fracture, it was curious that it should be symmetrical. He had examined very many bodies in the dissecting room at St. Bartholomew's Hospital, and found a similar condition in several.

MR. BRUCE CLARKE corroborated the observations of the last speaker as to this condition being found not infrequently in the bodies of old people, he thought that the condition was probably the result of rheumatic changes occurring towards the end of life.

THE PRESIDENT alluded to the position of the first rib, and said that being rigid it played the part of a "holdfast."

MR. LANE was quite familiar with the conditions mentioned by Mr. Lockwood and Mr. Clarke, but considered that his own specimen presented characters quite distinct.

Neoplasm of the Knee-joint.

MR. BARWELL described the case of a little girl, aged twelve, who had come under his care, suffering from an affection of the knee-joint. At first there had appeared to be a simple synovitis, but some months later it was evident that the case was one of malignant disease. Amputation of the thigh was therefore performed. The tumour was soft, jelly-like, and semi-transparent; it arose from the tuberosities of the tibia, and microscopically was mainly composed of a network of spindle-cells. He was desirous of pointing out that the distinction between carcinoma and sarcoma was not an absolute one. The former possessed an alveolar stroma, and contained epithelial cells, the other did not, but it was undoubted that a cancer might be followed by secondary growths of a purely sarcomatous nature. He considered that malignancy was a morbid entity, and might be carcinoma or sarcoma, according to the structure in which the growth originated.

MR. BUTLIN observed that the suggestion had often been made that all malignant growths should be included under one generic term, and subdivided according to their seat of origin.

DR. CREIGHTON could not agree with Mr. Barwell, that all sarcomas were infiltrating; many of them were surrounded with a capsule, and could be removed without any recurrence. As to the proposed term "cacoma" for all malignant growths, he thought it was a sufficient objection to it that it was cacophonous.

MR. GODLEE agreed with Dr. Creighton, that the term malignant could not be applied to all sarcomas. Myeloid tumours were often very benign, and at other times most malignant. True cancers (epithelial growths) were always malignant.

THE PRESIDENT said that Mr. Barwell would adopt two bases for the classification of tumours, one anatomical, the other clinical; such an arrangement would, in his opinion, be very inconvenient.

MR. BARWELL in reply said, that he was of opinion that all sarcomas were malignant, though in different degrees; even an epulis might infiltrate, and required very free removal. Subcutaneous sarcomas, too, might recur. The difference between malignant growths was only one of degree, and he emphasized his previous statement, that the secondary deposits in a case of true cancer were often pure sarcomata.

Insular Sclerosis.

DR. HALE WHITE showed specimens taken from a case of insular sclerosis. For twelve months before admission to the hospital, the patient had had nervous tremblings,

and subsequently to this weakness of the legs, which at last became so bad as to preclude walking. Latterly, her memory had been very deficient. She had always been a drunken dissolute woman. On admission, she was in such a moribund condition that a very thorough examination could not be made; but it was observed that there was tremor on movement, the right pupil was larger than the left, the grasp of the hands was feeble, and she spoke very slowly. She died shortly after admission. The necropsy was made 26 hours after death. In the left arachnoid cavity, and covering the greater part of the parietal lobe, was a hæmorrhage evidently recent; arteries at the base of the brain thickened. Scattered about in the white substance below the level of the corpus callosum were four grey patches, looking very like grey convolutions. The medulla was obviously diseased, many reddish-grey patches being present in it. The rest of the brain was healthy. In the spinal cord, many similar patches were scattered about in various parts, but chiefly in the crossed pyramidal tracts. In many places, the whole of the white matter of the cord was affected. The kidneys were granular and hypertrophied. Microscopical examination of the cord and brain showed characteristic sclerotic appearances. In many sections, it could be seen that the ingrowth of new tissue was directly connected with the rays of tissue prolonged in from the neuroglia on the surface of the cord; sometimes the axis-cylinder had completely disappeared, leaving the medullary sheath, and sometimes the medullary sheath disappeared, the axis-cylinder having alone remained surrounded by sclerosed neuroglia. It was pointed out that the chief feature of interest in the case was that it was almost a purely spinal one.

Dr. HADDEN thought that he had seen changes similar to these in a good many cases. The naked-eye appearances in a case of disseminated sclerosis were more important and far more characteristic than the microscopical ones; he agreed that there was some increase of fibrous tissue in the specimens.

Dr. WHITE, in reply, fully agreed with Dr. Hadden as to the much greater value of the naked-eye changes in these disorders, and this had been a very prominent feature in his case. One point of interest was, that the disease was almost purely spinal, which must be considered decidedly rare.

Interstitial Disease of the Ovaries.

Dr. NORMAN MOORE showed the ovaries taken from a married woman, aged 41, who died in St. Bartholomew's Hospital, under the care of Dr. Church, from cirrhosis of the liver. The liver showed an increase of fibrous tissue, with marked atrophy of the cells. The ovaries were large, smooth on the surface, and very dense; there was great thickening of the tunica albuginea, and of the perivascular tissue throughout the ovary. This was especially distinct in the zona vasculosa. Numerous compressed Graafian follicles were visible, both small and large. Dr. Matthews Duncan had suggested that this change in the ovaries was a cause of sterility in intemperate women. Mr. Lawson Tait had also mentioned cirrhosis of the ovaries, but the disease was rare, and had seldom been minutely described. The new fibrous tissue of the ovaries appeared more recent than that of the liver.

Dr. GOODHART asked if there had been any ascites present, as it had been suggested that in cases of ascites the ovaries might absorb fluid, and thus changes might be set up.

Dr. MOORE, in reply, said that there was a good deal of ascites, but the ovaries did not contain any fluid; it was worthy of note that the kidneys did not show any cirrhotic change.

Epithelioma of the Ear.

Mr. BOWLBY exhibited the ear of a man, aged 70, which had been removed for epithelioma. The disease commenced in the helix, and was attributed to an injury from some lime, three and a half years previously. When first seen there was an ulcer which had existed for a year and a half, during the next six months it spread to the concha and down towards the pinna. The whole organ was removed, but the growth had returned in the external auditory meatus, and in the glands in the neck. Microscopical examination showed how the cartilage was invaded, its matrix offering considerable resistance to the ingrowth, and becoming necrosed in small portions.

Mr. ROGER WILLIAMS exhibited a photograph of a similar case, and referred at some length to the cases already recorded.

Mr. GOLDING BIRD mentioned a case he had seen some years ago, the disease commenced on the top of the auricle, and there was no glandular enlargement; until the microscopical examination was made, the disease was thought to be rodent ulcer.

Mr. BUTLIN had seen three cases in all, including the present one; he had been surprised that the growth had returned so quickly, as the removal had been very free. In one of the other cases the glands were already involved before operation. The third case was that of an old man, in whom the disease was very limited, and the glands were not involved. There was no recurrence during the remaining three years of his life. In this case Mr. Butlin believed that the disease had commenced in a sebaceous cyst and had hardly spread. As a rule the disease was a very malignant one.

Fibrotic Disease of the Heart.

Dr. SAMUEL WEST showed this specimen taken from the body of a man, aged 40, during life he had been subject to spasmodic pain in the region of the heart, but the clinical history of the case was very imperfect. After his death, which took place suddenly, the viscera were found to be congested, the stomach and intestines showed some ecchymoses, and there was some thickening of the capsule of the liver. There were scars on the penis, presumably syphilitic. The heart weighed 20½ oz., the pericardium was healthy, the cavities were enlarged. On the surface of the left ventricle there were dense fibrous-looking patches, causing an almost granular appearance, this was less obvious on the right ventricle. On opening the heart, the left ventricle was found to be extensively affected, its walls were thinned and composed almost entirely of fibrous tissue, a sort of pouch being formed but not visible from the outside, the valves were healthy. The affected parts were dense and hard, the muscular tissue was slightly fatty. In the right ventricle there were similar but less extensive changes. The specimen was interesting from its being so extensively diseased, from the fact that no definite aneurysm had been formed, and from the probability that the man had had syphilis.

Symmetrical Gangrene with intrathoracic Tumour.

Dr. B. O'CONNOR showed a woman, aged 56, with this condition; pain in the fingers had been the first complaint, then they became blue, cold, and blisters had formed. Four years ago she had had a tumour of the right breast, which had been successfully removed. Three months ago she noticed a tumour in her left breast, and three weeks ago a swelling in her chest, and shortness of breath on exertion. The pain, smarting and burning, was suggestive of arteritis. The patient had also suffered from earache. There was dulness under the left clavicle with enlarged glands in the neck on both sides, especially on the left side. In the second left interspace was a globular swelling, dull on percussion, there was no thrill in it. There was no

dysphagia. There were no signs of heart-disease. There was a tumour in the left mamma, and the glands in the left axilla were enlarged. The liver could not be felt; the abdominal veins were not enlarged. The pulse at the wrist on the right side was visible. The urine was natural. There was slight increase of the white blood corpuscles. He discussed the question as to whether there was embolism or spasm of the minute arteries. The process evidently was not a very chronic one. It appeared that arteritis was more common in women than in men.

Mr. Bowlby could not see any evidence of vascular obstruction in this case. The history pointed rather to nerve disorder, and the fingers closely resembled the condition which was seen after section of the nerves. The new growth pressed rather upon the nerves than the arteries.

Living and Card Specimens.

Mr. H. H. Clutton. A man with primary sarcoma of the tonsil.

Mr. Lockwood. Right aortic arch.

Mr. Golding Bird. Micrococci from infective osteomyelitis.

Dr. F. C. Turner. (1) Tuberculosis of lungs, caseous bronchial glands and tubercular meningitis after scarlatina. (2) Intus-susception of the small intestine with polypoid fatty tumour.

Mr. H. H. Clutton. (1) Nasal calculus. (2) Central myeloid sarcoma of the tibia which produced no expansion of the bone.

Mr. J. Hutchinson, jun. (1) Ankylosis of second and third cervical vertebræ. (2) Superior vena cava on the left side.

Dr. J. F. Goodhart, for Dr. Pye Smith. Chronic ulceration and thickening of tracheal mucous membrane from the presence of a rubber tracheotomy tube.

Dr. R. Percy Smith. Stomach from a case of sulphuric acid poisoning.

Dr. Seymour J. Sharkey. (1) Two vertebræ of a small fish which had been impacted in the larynx, and removed by tracheotomy, the child, aged one year, died of double pneumonia. (2) Œsophagus, stomach and intestine from a case of poisoning by carbolic acid.

Dr. Samuel West. Stomach from a case of carbolic acid poisoning.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Saturday, March 1st, 1884.

John Marshall, F.R.S., President, in the Chair.

The Annual Meeting of this Society was held on Saturday evening last. The President took the chair at 8 o'clock, and declared the ballot open for the election of officers for the next year, and nominated Mr. Christopher Heath and Dr. Bernard O'Connor as scrutineers. At the close, the President announced that the gentlemen nominated by the Council had been duly elected. (The list of names was published in our issue of last week.)

Dr. Douglas Powell then read the report of the President and Council. The Society was congratulated on the continued prosperity of its affairs, and on the increase of the number of its Fellows, who now numbered 720, including honorary, resident, and non-resident Fellows. During the past year, eighteen Fellows had died, and three had resigned; while 35 new Fellows had been added. The expenditure had somewhat increased; this was due to the augmentation in the salaries of the resident librarian, and some other officers, and in part also to the increased cost of publishing the proceedings, which, in addition to abstracts of the papers, now included verbatim reports of the speeches made at the meetings throughout the session. Furthermore, the abstracts of the papers were distributed amongst the Fellows previous to being read. The advantages of these changes were evidenced by the larger number of Fellows who took part in the discussions, and by the increased interest to which they gave rise. The session had opened with an oration from Dr. Ferrier, on the progress made during the past few years in the study of the physiology and pathology of the nervous system, to which he (Dr. Ferrier) had so largely contributed, that the Council had last year awarded him the second Marshall-Hall Prize. The library was reported to be in a flourishing condition. Four hundred and sixty-one works had been added during the preceding year. These additions included some valuable books from the library of the late Sir Thomas Watson, presented by his son, Sir Arthur Watson. An alteration in the by-laws would be proposed (it was subsequently passed), by which honorary resident Fellows were to be allowed the use of the reading room and library on the same terms as the ordinary Fellows of the Society. The Council expressed their deep regret at the loss they had sustained by the death of their late resident librarian, Mr. R. B. Wheatley. They were thus deprived of a most devoted and efficient officer, of unequalled skill in his profession. When about to fill up the vacancy thus created, they received applications from 93 candidates, and after very careful consideration their choice had unanimously fallen on Mr. J. B. Bailey, a member of the Association of Librarians, who for sixteen years past had served as sub-librarian at the Radcliffe Library at Oxford.

Mr. John Wood proposed the adoption of the report; this was seconded, and carried unanimously.

The President then gave his usual address. He first alluded to the losses which the Society had sustained, and he read a brief memorial *éloge* on each of the Fellows. The list included Dr. Hudson, Dr. Evans, Dr. F. H. Wilson, Dr. Marion Lewis, Mr. McNaught, Dr. Gully, Mr. Harding, Dr. Colomiati Meredyth, Dr. Hilton Fagge, Dr. Robert Druitt, Mr. Phillips, Dr. Stewart, Dr. Jones, and Dr. William Farr, C.B., F.R.S. He next adverted to the origin and growth of the various scientific societies, both in London and in the Provinces, pointing out how they went hand-in-hand with greater activity in professional work, and with a remarkable increase in medical literature. He also referred to a possible amalgamation of the society with some of the other societies; he thought, however, there were many insuperable difficulties in the way at present. Dublin had recently effected an amalgamation of the Medical Societies; but the conditions were quite different from our own—the numbers concerned in Dublin were only about one quarter of those who formed the London societies; and the difficulties would be great in proportion. The President then thanked the Society for the honour they had twice conferred upon him in electing him president; he hoped that continued prosperity would attend them.

Mr. Savory then proposed a vote of thanks to the retiring President for the very efficient manner in which he had discharged the duties of this arduous office. This was seconded by Dr. Day, and carried by acclamation.

Dr. W. Overend Priestley next proposed a vote of thanks to the retiring Vice-President (Dr. Russell Reynolds), and to the other retiring Members of Council. He spoke of the labour and attention entailed in the discharge of these duties, and of the very prosperous condition of the Society. This was seconded by Mr. R. W. Parker, who said that the vote was specially due in acknowledgement of the increased activity which had marked the meetings during the past two years. The vote was carried unanimously. This concluded the ordinary business of the Society.

Dr. Wilson Fox, one of the honorary librarians, then rose to suggest some memorial by the Fellows in appreciation of the long and faithful services of their late resident librarian. "Mr. Wheatley," he said, "had dependent upon him during his life a sister and a niece: it had always been with him a matter of great anxiety that they were not provided for; he proposed, therefore, that a subscription list should be opened, and that the proceeds should be expended in the purchase of an annuity for these ladies. Mr. Wheatley's long continued and zealous services to the Society—services which were rendered to all alike without distinction—were so well known and so fully appreciated, that he had little doubt that the Fellows would come forward and assist in carrying out a work, which would be so much in accord with Mr. Wheatley's own desires, could he have

been consulted in the matter. Mr. Savory warmly seconded this resolution, and it was carried unanimously. A subcommittee (with power to add to their number) was then appointed, to consist of the President (Dr. George Johnson), Mr. Marshall, Mr. Savory, Mr. Hulke, Dr. Wilson Fox, Mr. Cooper Forster, and Mr. Berkeley Hill. The presidents of the Pathological, Clinical, and Obstetrical Societies were to be invited to join them.

The Society then adjourned.

ACADEMY OF MEDICINE IN IRELAND.

Surgical Section.

The Radical Cure of Hernia.

Mr. Wm. Stokes (Professor of Surgery, Royal College of Surgeons) read a paper on "The Radical Cure of Hernia by Peritonæal and Intercolumnar Suture." Having alluded to the fact that the subject of the radical cure of hernia had, from remote antiquity to the present, engaged attention, he mentioned that, although it could not be said definitely that the wished-for goal had been attained, still, thanks to Listerism, much had been gained. In proof of the fact that the feasibility of obtaining radical cures by operation is a question *sub judice*, he referred to the writings of various eminent surgical authorities, some of whom are opposed to, and others in favour of, such attempts being made. The object of the various operations hitherto performed, namely, obliteration of the neck of the sac, with approximation and union of the tendinous structures about the hernial passages, and also the methods of "dissection," were discussed; and the author believed that the method recently adopted by himself and his colleagues was simpler and more efficacious than any of those he mentioned. It consisted in the insertion through the open neck of the sac, and close up to the external abdominal ring, of a deeply indented carbolised catgut suture or sutures, according to the size, width, and depth of the neck, and this is followed by the approximation or closing of the canal and pillars of the ring by the insertion of two or more sutures of a stronger or more durable material, such as chromicised catgut, gilt or silver wire. In fact it was a dual system of suture, one being peritonæal, and the other intercolumnar. Four cases were recorded in which this plan was adopted. In three of these successful results were obtained. The unsuccessful case was one of congenital inguino-scrotal hernia. The hernia reappeared three months after the operation. The failure was probably due to his not having used a sufficiently durable material for closing the pillars of the ring, that which the author employed being chromicised catgut. In future he would employ in similar operations either carbolised silk or silver wire.

Mr. Barton read a paper on the same subject. At the outset he laid down the principle of treatment, viz., that the internal ring should be so effectually closed as to prevent the hernia coming down into the canal at all. He described Wood's operation as a combination of this and of the old plan of invagination, which latter should be discarded, and the closure of the ring perfected. The direct operation was recommended, refreshing the edges of the ring, as recommended by Gross, or cutting away the sac, as practised by Czerny. Three cases were related —(1) that of a boy, aged three, who had a hernia as big as a cocoa-nut, which could not be held up by any truss; (2) that of a young man who had been rejected at the physical examination at Sandhurst for a small inguinal hernia; and (3) a child, three years old. In all three the internal ring was closed with silver wire, which was left in, but in the first case it had to be removed subsequently, as the wound reopened. The result was, that in the first case the child left the hospital with a truss, but the hernia again came down. In the second case the result was satisfactory, and the patient was admitted to Sandhurst. In the third the child was exhibited, but sufficient time had not elapsed to pronounce upon the result. The cases proved—first, that the operation was readily performed; secondly, that (with antiseptic precautions) it was safe; and thirdly, that it was advisable, if not directly necessary, to retain the wire sutures *in situ*.

Mr. Kendal Franks also read a paper on the same subject, by the method of dissection, the name which has aptly been applied to it in Dublin. The only two methods which seemed to him to give promise of extensive application in the future were:—(1) Suture of the abdominal openings without removal or ligature of the sac; and (2), suture of the abdominal openings after excision of the sac. The first of these operations was applied to a recent hernia before the sac had had time to become enlarged and thickened. The method consisted essentially in cutting down on the tumour, carefully exposing the sac, which should be returned into the abdomen, and then drawing together the openings by means of two or three sutures of stout silver wire, which should be left permanently in position. He advised that the skin should be drawn slightly upwards before the first incision was made, as by that means the skin would not be directly over the wires. Thus union by first intention was promoted, and the permanent retention of the silver wire assisted. Three cases were related in which this method was employed: Case 1. Medical student, aged seventeen, presented a direct inguinal hernia of the right side, which had suddenly made its appearance after a long run of six miles a few days before; the operation was performed on April 1st, 1882; the wound healed by first intention, and the dressings were discontinued on the eleventh day; he wore a light truss for sixteen months, but since August 1st last had given it up; he had had no return of the hernia, and never experienced any trouble from the wires, though within a year after the operation he won a four-mile bicycle race. Case 2. A man, aged 24, of intemperate habits, suffered from an oblique inguinal hernia of the right side, the result of a fall off a car. The operation was performed 3rd July, 1882, but owing to the excitable restlessness of the patient it was found impossible to keep the wound aseptic, and a fortnight later it was necessary to remove the wire sutures. The wound healed by granulation, and the patient left the hospital without any tumour. Subsequently, however, the hernia returned, and though it was reduced in size, it descended somewhat into the scrotum. The patient could not be induced to wear a truss. Case 3. A gentleman, aged 21, had suffered for two or three years from a small oblique inguinal hernia of the right side. As it was increasing in size, he was operated on on May 1st, 1883. two silver sutures being employed. Two dressings only were applied, the wound being completely cicatrised before the eleventh day. He went out driving on the twelfth day, and during the summer used to bathe without a truss. He had not since had any return of the hernia, and there was not any impulse. The second method had a wider scope, and was applicable even to cases of complication which would have rendered any other operation impossible. In the case of a man, aged 50, the subject of a large direct inguinal hernia of the left side, measuring six and a half inches in the longitudinal and three inches in the transverse diameter, the operation, which was performed February 1st, 1883, showed that the thickened sac was adherent in its whole length to the spermatic cord, which was spread out in a thin layer over its posterior surface. The sac was cut across, about an inch below the deeper opening in the abdominal wall, which readily admitted the tips of three fingers. Three stout silver sutures were passed through the structures forming the external and internal openings, including the peritonæum on both sides, and by drawing them firmly together and twisting the ends the openings were completely closed. As much of the sac as it was possible to dissect away from the cord was removed. The wound healed by first intention, and the patient made a good recovery, in spite of a hæmatocele which occurred on the second day, as a result of the patient's walking about the ward the night after the operation. When last seen, on April 7th, there was no sign of the hernia and no impulse.

Mr. W. Thornley Stoker said there were two distinct classes of cases—the class in which an operation was compulsory, where strangulation existed, and the class where operation was a matter of election to promote the patient's convenience rather than save his life. In nearly all cases of operation for femoral hernia a permanent cure had been

effected; but in large inguinal ruptures a radical cure was not so frequent, and in such cases the peritonæum should be sutured. In the second class of cases he advocated Wood's operation. He did not think it mattered much whether the pillars of the ring were drawn together or not. A cure was effected by the inflammation exciting the exudation of coagulum and lymph, which drew the parts together, thereby closing the opening as with a cork. He protested against leaving in the wire suture where the ring was sutured, in inguinal hernia, as most unscientific and unsurgeon-like, and a possible source of future trouble.

The PRESIDENT mentioned the result of nine cases in which he had operated by different methods. In a case of inguinal hernia on the left side in a male, he exposed the neck of the sac. He then drew it down and applied a ligature, divided the neck and removed the sac below the ligature. This case was successful when seen two years afterwards. He performed a similar operation in the case of a female suffering from a small inguinal hernia in the centre and above Poupart's ligament, which became strangulated; and she was perfectly cured, having been seen five years afterwards. In a femoral hernia on the left side in a female aged eighteen, he opened the sac, pulled down, excised, and closed the edges, and the result eighteen months afterwards was most satisfactory. He adopted the dissection method in other cases, but without improving the hernia. In cases where the canal was greatly distended by a large hernia, it would be almost impossible to have a radical cure follow any radical measure, and the most likely was by excision of the sac.

The discussion was then adjourned.

At the adjourned meeting, Mr. ORMSBY said that many of the present operations were, with few exceptions, old operations revived under new names. Mr. Stokes' procedure was bold and somewhat heroic; but with the aid of antiseptics and a complete regard to the details of Listerism, operations in abdominal surgery might be performed with the greatest impunity. Having unsuccessfully attempted to cure by the radical method following the plans suggested by Wutzer, Wood and Gerdy, he himself devised a plan eighteen months ago, and carried it out successfully in the case of a young man, aged 26, who suffered from oblique inguinal hernia (reducible). The hernia was reduced and the skin and cellular tissue of the scrotum invaginated and pushed up with the finger as high as possible through the external abdominal ring into the inguinal canal. Then a flat needle, with handle attached, armed with a stout piece of silk ligature, was passed along the finger fixed in the inguinal canal, and made to pierce upwards and outwards until it passed through the anterior wall of the canal, so that the eye of the needle was apparent through the skin. The end of the ligature having been caught and secured, the needle was withdrawn. The other end of the same silk ligature was then inserted into the needle which was passed up along the finger still fixed in the inguinal canal, and passed through the anterior abdominal wall as before. The two ends of the ligature were then drawn up and tightened, and a small piece of bougie about two inches long placed between the two ends of ligature which were tightened and tied firmly across the bougie close to the point where they emerged from the skin. A glass rod having been placed in a solution of liquid ammonia, was passed into the invaginated canal, so as to abrade the surface and excite adhesive inflammation or ulceration, and thus finally obliterate the canal. Lastly, a harelip pin or accupressure needle was passed deeply through the tissues transversely to the inguinal canal at a point midway between the external abdominal ring and the position of the ligature tied over the bougie. Care must be taken not to pass the needle behind, but immediately in front of the cord. A ligature was then placed over the two ends of the pin or needle, compressing firmly the intervening tissue, the pin or needle to remain until it ulcerated its way out. The ligature over the bougie was also allowed to ulcerate its way out. In Mr. Franks' cases, he would prefer to use chromicised gut instead of silver wire, which he would on no account leave embedded in the abdominal wall lest trouble might ensue.

Mr. CORLEY was of opinion that the direct operation by dissection was better in theory, and more likely to succeed in practice, than Wood's. It appeared to him that Gerdy's, Wood's, and such like operations were blindfold or ostrich surgery. There could be no doubt that in strangulated hernia the operation ought to be the radical one. Thinking over why some cases were successful and others not, he remembered that Lawrence, in his book on ruptures, published in 1838, had remarked that one of the predisposing causes was an elongated condition of the mesentery and a lax condition of the peritonæum; and the same author detailed a number of methods for the radical cure, one of the earliest and mildest operative procedures being incision, *i.e.*, dividing the integuments and opening the sac after the integuments had been replaced, and then dressing the wound, so that it should heal by granulation. That was, practically speaking, the operation by dissection. The point to be considered in connection with the radical cure was, how far interference was justifiable.

Mr. HAYES mentioned that he had, twelve years ago, performed Wood's operation with satisfactory results in the case of a female who suffered from inguinal hernia, which could not be adequately supported by a truss. She got married, bore three children, and was seen ten years afterwards perfectly free from danger of hernial protrusion. In the case of a youth, he performed the same operation, but the boy had to wear a truss. An operation was employed in America, to effect the radical cure by the injection of some irritating fluid within the inguinal canal and round the abdominal ring; and Dr. Warren had introduced the procedure at Guy's Hospital, operating upon a case of Mr. Bryant's, which did well. Mr. Bryant wrote that the man wore a truss afterwards, and six months later the hernia had not come down. He did not, however, perform the operation himself, as it seemed a mere matter of chance where the injected fluid went, and he preferred the operation by dissection.

Mr. THOMSON said the question always to be determined before undertaking the operation of dissection was, what was the risk to the patient—was it justifiable to subject the patient to a risk, whatever it might be, by cutting down upon the hernia, or cutting away the sac with portion of the peritonæum, when perhaps he could get on satisfactorily by the use of a well-adjusted truss? But there was the preliminary question, whether the patient, especially if in the lower walks of life, would not run a greater risk of strangulation of the hernia and death, than by an operation performed under favourable conditions. His impression was, that where the case was prepared properly, and in all respects favourable for operation, the patient would have a better chance of life by the operation to relieve him of his hernia. As to the material to be used in stitching the pillars of the ring, he operated on a case of enormous scrotal hernia of 25 years' standing, without stitching the ring, there being a fair stump that acted as a plug for the opening, and the result was satisfactory. The result of his experience in children was, that he would not use chromicised catgut to ligature the pillars of the ring. He objected to catgut, and preferred wire or silk.

Dr. WARREN was certain that the operation by dissection would be *par excellence* the operation of the future. He saw no objection to leaving in the wire suture.

Dr. BALL said he proposed an addition, carrying out an addition to the operation by dissection in a case he had under treatment in Sir Patrick Dun's Hospital—namely, by torsion of the sac, so that portions of the neck of the sac in the inguinal canal would be occluded.

Mr. O'GRADY called attention to an accident that befel him in an operation, several years ago, on a young fellow. He had made an incision in the skin, invaginating the superficial tissues underneath, and sewing these and the pillars of the ring together. Nothing untoward attracted attention at the time of the operation; but after some days the wound suppurated, large quantities of urine were discharged from it, and the child died. It was obvious that the needle had gone through the bladder. To obviate a similar result in all future cases, he emptied the bladder. Mr. Thomson's argument in favour of operative procedure was brought home to himself on two occasions recently when he was telegraphed for and his visit countermanded.

Dr. Foy, Mr. Nixon, and Dr. Ashe having taken part in the discussion, the authors of the papers respectively replied.

Mr. Stokes said, a surgeon would not be justified in sacrificing the testicle until he was satisfied that its function was destroyed. He had determined, undeterred by the discussion, to use metallic sutures in his next case. He denied that Wood's operation was haphazard.

Mr. Barton said the question, whether invagination ought to be superseded by the plan of direct closure of the ring, would be decided by the future record of operations. He should continue to employ metallic sutures, taking care as to their being safely placed.

Mr. Franks referred to Buchanan's method of treating children by bandaging them in a St. Andrew's cross as very successful. In operative procedure the open had an enormous advantage over the closed, the surgeon being able to see everything he did. He did not agree with Mr. Thornley Stoker as to the condition of lymph sufficing to approximate the rings. It could not be so efficacious as the additional obstruction afforded by the wire, the objections to which were only theoretical.

The section then adjourned.

OBITUARY.

STEVENSON BUSHNAN, M.D.

The death of Dr. Stevenson Bushnan will cause old readers of the *Medical Times* to recall the early history of this journal, and to lament the loss of one who once held towards it the most important and prominent position. When, in 1851, Dr. Alfred Swaine Taylor, who succeeded Dr. Robert Willis as editor of the old *Medical Gazette*, resigned the editorial chair of that journal on its ceasing to exist as a distinct publication, Dr. Bushnan, who had held the editorship of the *Medical Times* since 1849, was appointed editor of the new paper—the *Medical Times and Gazette*. Every man connected with the literary work of both journals went over to the new editor, and Taylor wrote to many of the more active of his old contributors, expressing confidence in his successor. A painful defect of speech prevented Dr. Bushnan from being all that he himself desired to be; but he made up for this defect by his admirable courtesy, generosity, and fairness of judgment. After remaining at his post for a few years, Dr. Bushnan determined to leave literature and to become resident physician to the Laverstoke House Asylum, Salisbury. Here, for many years, he had ample opportunity of following the artistic and classical pursuits in which he delighted; but, unhappily, as age advanced, he became too soon unfitted for active work, owing to failure of his eyesight; and, having made but little provision for himself, was obliged to retire near to Southampton, and to live in a much simpler and plainer way than he had been accustomed to in his better days. A few years ago, by the exertions of one or two old friends, he became a resident brother in the Charterhouse. His death took place, after a protracted illness, on Sunday, February 17th, 1884.

Dr. Bushnan was a Doctor of Medicine (by examination) of Heidelberg, and a Fellow of the Royal College of Physicians of Edinburgh. He took his first diploma at the Royal College of Surgeons of Edinburgh, in 1830, and was for a time Senior Physician to the Metropolitan Free Hospital. He was the author of several valuable papers and works; one of his first essays, published in 1833, being on "Parasites in the Blood," a study which "he commenced with spirit and ended with promise." In 1837, he wrote "The Philosophy of Instinct and Reason;" and in 1851, he indulged in a contest relating to the eminent Harriet Martineau. In 1854, he was busy contributing to *Orr's Circle of the Sciences*, a work which enjoyed considerable popularity; and in 1860, he wrote "Religious Revivals in Relation to Nervous and Mental Diseases." The works are all characterised by an extended knowledge of mental phenomena and a genial style.

GENERAL CORRESPONDENCE.

THE MEDICAL BILL.

[To the Editor of the Medical Times.]

Sir,—With reference to the Medical Bill, the following few remarks may not be inappropriate to the attention which is rife between the medical licensing bodies. In the competition for the public services all medical graduates meet on equal terms, and as the army draws the largest number, I have taken from the Army Lists, from 1862 to 1883 inclusive, the names and qualifications of the two gentlemen at the head and of the two at the bottom of the ranks at each examination for this period. There are 66 in each category. In the case of an individual belonging to different corporations, I give the first registered as the one to which the party is assigned. The result is the following, viz.:—

	Top.		Bottom.
Royal College of Surgeons, England	20	..	10
English Universities	4	..	1
Royal College of Surgeons of Edinburgh	5	..	6
Scottish Universities	11	..	12
Dublin University	7	..	7
Queen's University in Ireland ..	14	..	8
Royal College of Surgeons in Ireland	5	..	22

It will be seen from these facts what corporation produced the highest percentage of good men and what of mediocre men at the army test. Genuine medical reform should be directed towards obtaining Poor Law, Prison, Lunacy, and Sanitary medical officers by competitive examination open to all graduates, promoting to inspectorships through the respective departments, and leaving the teaching and licensing bodies free. The public will in their own instance select the fittest according to fancy, judgment, and other influences.

Yours truly,

JOHN ROCHE, M.D.,
R. In. Med. Service.

Mount Clarence, Kingstown.

PRIMARY LATERAL SCLEROSIS OF THE CORD (?).

[To the Editor of the Medical Times.]

Sir,—The last number of your valuable journal contains a paper by Dr. Russell, of Birmingham, on "Cases of Spinal Disease," in which it is stated that Dr. Dreschfeld, of Manchester, "has at last, by anatomical evidence, settled the question of the existence of such a disease as primary sclerosis of the lateral columns of the cord." I find the same statement in the second edition of Dr. Ross's able "Treatise on Diseases of the Nervous System" (vol. ii., p. 71), where the author attributes to his colleagues, Professors Morgan and Dreschfeld, "the honour of having been the first to prove by dissection the connection of the symptoms of spasmodic paralysis with lateral sclerosis in a primary and uncomplicated case of the disease;" and says that "they found symmetrical sclerosis of the pyramidal strands, and *an entire absence of any other lesion*" (l. c. p. 82).

As these statements, emanating as they do from well-known neurologists, are likely to prejudice a question which is still completely unsettled, I shall feel obliged if you will allow me to remark that the account given by Dr. Dreschfeld, first in the "Transactions of the International Medical Congress," and afterwards in the *Journal of Anatomy*, does in no way support the view taken by Drs. Russell and Ross; for it shows quite clearly that the case of which so much has been made, was not one of uncomplicated lateral sclerosis, inasmuch as not only the white pyramidal column, but also the *giant-cells of the grey anterior cornua were found to be diseased*. These cells are stated "to have been wasted from the upper dorsal region down into the lumbar portion of the cord. There was simple atrophy, pigmentary atrophy, and occasionally complete absence of whole groups

of these cells." It is difficult to understand, after such a plain statement, why this case should constantly be quoted as an uncomplicated instance of primary lateral sclerosis.

All the other cases bearing on this point, and recorded by Charcot, Pierret, Schultz, Hopkins and others, are equally unsatisfactory; and it must be confessed that the disease in question has, as yet, eluded the grasp of the pathologist. It, therefore, appears to me preferable to employ rather the clinical name of "spastic paralysis," than the anatomical one of "primary lateral sclerosis;" as the former does not, like the latter, commit us to any definite theory which, for the present at least, is entirely unsupported by pathological evidence.

I am, Sir,

Your obedient servant,

JULIUS ALTHAUS, M.D.

48, *Harley Street, February 25th*, 1884.

INVENTIONS AND IMPROVEMENTS.

SCOTT'S MIDLOTHIAN OAT FLOUR.

It is admitted on all hands that oats possess much more valuable properties as a food-stuff than any other form of cereal, but as ordinarily prepared they contain too much vegetable fibre to serve as the main element in the food of any people but those with the strongest digestions. Of course where the bowl of coarse oatmeal porridge is taken every morning, "dietetically" as the euphonism has it, the woody fibre is an important element, causing just that slight irritability on the part of the intestinal mucous membrane, which is necessary to healthy periodical action. But if oat flour is to take the part in the dietary of infants and invalids, to which its flesh-forming properties entitle it, it must be freed from all indigestible matter. It is professed that this is done in Scott's Midlothian oat flour, an analysis giving only three parts per 1,000 of vegetable fibre. The flour is a fine impalpable powder, with the characteristic flavour of the oat; it makes a very palatable and digestible porridge, but one that is somewhat too gelatinous for healthy appetites. For infants and invalids this quality, however, would be a recommendation.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, February 28, 1884:—

Boyd, Joseph Thos., Northcote Road, Wandsworth Common.
Brooks, Jabez Pratt, Tollington Park, N.
Hayward, Arthur Ernest, Maxilla Garden, Notting Hill, W.
Hichens, Frank, Redruth, Cornwall.
Morinni, Wm. Raoul de, Myddelton Square, E.C.
Plowman, Sidney, St. Thomas' Hospital.
Satchell, Chas. Geo., Caversham Road, N.W.
Simms, Henry, Pedmore, Stourbridge.

The following gentlemen also, on the same day, passed their Primary Professional Examination:—

Michell, Jno. Chas., The London Hospital.
Roberts, Hugh Jones, Guy's Hospital.

The Dublin Sanitary Association.—The eleventh annual report of this useful voluntary Association was submitted to a general meeting of the subscribers and supporters, held on Thursday, February 21st, in the Leinster Hall, Molesworth Street, Dublin. Mr. Jonathan Pim, president, occupied the chair. From the report, it appears that the association numbers 237 members, and the income for the year amounts to 147*l.* 1*s.* 1*d.* Unfortunately, the expenditure was decidedly in excess of the income, so that there is now a small balance against the association. The chief topics touched upon in the report were the approaching congress of the Sanitary Institute of Great Britain in Dublin next October, the progress of the "sanitary protection" branch of the association, which is now in full working order, the sanitary survey of the city, recently undertaken by the public health committee of the corporation, the insufficient collection of fines imposed for breaches of the sanitary laws, the premature discharge of patients from fever hospitals, the notification of infectious diseases, the overcrowded condition of tenement houses, the inaccessibility of the public health office of the corporation, the continued existence of slaughter-houses in the city, the reopening of houses closed as unfit for habitation, and the death-rate of Dublin. The death-rate in Dublin for the year 1883 was 29·1 per 1,000, as compared with an average rate of 28·9 for the ten years preceding. A table was appended showing the rates in the six largest English and Scotch towns for the same period, from which it appears that Dublin retains its position as the most unhealthy of the great towns of the United Kingdom. The adoption of the report was moved by Dr. William Moore, president of the King and Queen's College of Physicians, seconded by Mr. Robert O'Brien Furlong, solicitor to the Inland Revenue Department, and unanimously agreed to.

University of Dublin.—*School of Physic in Ireland.*—At the Hilary Term Examination for the Degree of Bachelor of Medicine (M.B.), held on Monday, Tuesday, and Wednesday, February 11th, 12th, and 13th, the successful candidates passed in order of merit, as follows:—Ninian M. Fleming, Charles R. Kilkelly, William B. Day, Thomas Lyndon, Charles H. Blood, William S. Boles, Victor E. Smith, John Cochrane, Richard G. Hanley and John S. A. Ireland equal, George W. Yeates.

University of Dublin.—At the Hilary Term commencements, held in the Examination Hall of Trinity College, Dublin, on Shrove Tuesday, February 26, 1884, the following degrees in medicine and surgery were conferred by the University *Caput* in the presence of the Senate:—*Baccalaurei in Chirurgia.*—Blood, Carolus Holcroft; Boles, Guilelmus Samuel; Cochrane, Johannes Jacobus; Fleming, Harloe Henricus; Hanley, Ricardus Georgius; Ireland, Johannes Stewart Algeo; Kilkelly, Carolus Randulphus; Lyndon, Thomas; Smith, Victor Eduinus; Yeates, Georgius Wyclif. *Baccalaurei in Medicinâ.*—Falkiner, Ninian M'Intire; Grant, Carolus Scovell; Ireland, Johannes Stewart Algeo; Lyndon, Thomas; Power, Carolus Johannes; Smith, Victor Eduinus; Tatham, Johannes Franciscus Walkingame; Thompson, Carolus Herbert; Windle, Reginaldus Joscelyn; Yeates, Georgius Wyclif. *Doctores in Medicinâ.*—Grant, Carolus Scovell; Power, Carolus Johannes.

Army Medical Department.—Surgeon-Major S. K. Ray has been appointed to succeed Surgeon-Major Gasteen, in the command of the Army Hospital Corps Depôt and Training School at Aldershot. Deputy-Surgeon-General R. Wolseley, M.D., has been ordered to Aldershot, to take over the duty of Sanitary Officer of the Division, vice Deputy-Surgeon-General J. J. Thompson, ordered to Dublin. Surgeon-Major P. W. Stafford has been appointed a member of the Permanent Committee on Dress and Equipment, of which Colonel R. Harrison, C.B., C.M.G., is President, vice Surgeon-Major W. C. Gasteen, ordered abroad. Surgeon-Major Charles Edward Wikeley, retired pay, has been granted the honorary rank of Brigade-Surgeon. Surgeon-Major Daniel Murray, M.D., is granted retired pay, with the honorary rank of Brigade-Surgeon.

The Hospitals' Association.—The first Council of the Association contains the following members of the profession: Sir Andrew Clark, Sir Rutherford Alcock, K.C.B., Dr. H. W. D. Acland, C.B., Dr. Bristowe, Mr. Henry C. Burdett, Dr. R. Farquharson, M.P., Mr. Timothy Holmes, Dr. R. H. Lloyd, Mr. Charles Macnamara, Mr. Malcolm Morris, Dr. Quain,

and Dr. Gilbart Smith. It is proposed that the evening meetings of the Association shall be held on the third Wednesday in the month. The first, however, will take place on the 26th March, when a paper will be read by Mr. William J. Nixon, house governor of the London Hospital, on "Difficulties Associated with the Administration of the Out-patient Department, and How Best to Deal with Them." The meetings will probably be held at the rooms of the Medical Society of London, Chandos-street, Cavendish-square, the chair being taken at 8 p.m. Persons desirous of being present at the evening meetings, or becoming members or associates, are requested to communicate with the Secretary, Mr. J. Clifford Smith, at the office, No. 1, Adam-street, Adelphi, who will gladly forward the necessary forms of application.

GREIG, CHARLES, F.R.C.S., at 16, York Place, Clifton, Bristol, on February 27.

HART, W. H., M.R.C.S., L.S.A., at 14, Springfield Place, Bath, on February 27, in his 26th year.

MADDEN, H. R., M.D., at 1, Bloomfield Place, Bath, on February 29, in his 66th year.

REMINGTON, THOMAS, M.D., formerly of Brixton, on March 2, aged 67.

NOTES, QUERIES, AND REPLIES.

THE MARRIAGE OF COUSINS.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—To answer the question of "J.B.W.," at page 307, of your last issue, would occupy far too much of your valuable space. The views of different observers (or rather writers) may be consulted by a reference to section 563 of the "Medical Digest," and since the publication of this work, in 1882, the following papers have appeared: Dr. Liebreich, *Medical Times and Gazette*, vol. i, 1861, p. 372 (*this was omitted before*); Dr. Cameron, *British Medical Journal*, June, 1883, p. 913, and September, 1883, pp. 456 and 608; Dr. Hooper, *Lancet*, December, 1883, p. 1107, also p. 88, June, 1883. In the case "J.B.W." cites, all the writers would agree, I think, in condemning such a marriage.

Obediently Yours,
RICH. NEALE, M.D. Lond.

T. A. Dixon, Esq., Kingston, Jamaica.—Subscription does not expire till July 20, 1884.

Dr. Williams.—The lectures by Professor Flower at the College of Surgeons will be brought to a close on Friday next, the 14th inst. Mr. F. S. Eve, F.R.C.S., the "Erasmus Wilson" lecturer, will commence his "Demonstrations on Some Points in Pathology, illustrated by Specimens from the Museum," on Monday, the 17th inst.

H. M., St. Thomas's Hospital.—The memorials of John Flint South, twice President of the Royal College of Surgeons, are just published by Mr. Murray, and will no doubt contain what you are so desirous of knowing. So long ago as July, 1853, Mr. South moved in the Council that Mr. Edward Arris and Mr. Gale, having severally given the sum of £250 and a house on Snow Hill, for the endowment of lectures on anatomy, and such monies having been improperly merged into the general property of the College, it is due to the memories of the said founders, and as encouragement for similar endowments, that such appointments be revived.

BEING THE GULSTONIAN LECTURES DELIVERED AT THE ROYAL COLLEGE OF PHYSICIANS, LONDON,

By T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., F.R.S., F.R.C.P.,

Senior Physician to the Leeds General Infirmary.

LECTURE I.—[Abstract.]

THE lecturer said that he intended to deal more especially with such neuroses of the viscera as were manifested in pain. In the text-books these affections had not received the full treatment that their difficulties and importance demanded, and in general practice the part played by the nervous system in visceral disorders was insufficiently seen. Neuroses above the belt were apparently far better understood than those below it, a fact partly due to the impulse given to the study of thoracic disease by the discovery of Laennec, and partly to the more vivid functions enjoyed by those parts, as compared with the brooding and silent life of the organs of vegetative existence. His attention would be almost entirely confined to the pains and storms of the lower or abdominal regions, and he would say but little of the neuroses of the upper chambers. As to the neuroses of the viscera of the pelvis, which had received an attention of too exclusive a bearing, he would deal with them by way rather of illustration than of description.

The first strong impression he had received from the facts of the class with which he was about to deal, was obtained from the index of his case-books, where he was struck each year by the small number of cases entered as dyspepsia. "How could this be?" he asked himself repeatedly. Martyrs to dyspepsia were to be found at every street corner. He thought of the stomach and its work, of the greediness or recklessness which made it the helpless receptacle of all sorts of rubbish; he pictured to himself that viscus distended with greasy, acidulous or trashy matters sodden in half-fermented gooseberry juice or sour claret, and stood amazed that it not only resisted destruction, but patiently drew order out of disorder, and sweetness out of foulness. In the journals he read of men of lofty endowments whose lives became accursed by dyspepsia, and in other sheets he found many columns of advertised solace, from wind pills, to the pills of the American doctor, the virtues of which had been thus rendered—

> Hæc jecur instigat, stimulos hæc renibus addit,
> Ambulat arcanas hæc taciturna vias;
> Attamen hæc eadem latebras penetralibus imas
> Mordacis buxi more modoque petit.

The medical journals and the lists of the large drughouses told of the same cry for help against the demon of dyspepsia, while patients were so confident

of the form of their enemy, that they dictated their own diagnosis to the physician, and demanded his specific. How could we explain this catholic wailing over a disease that is not? Was there in the word dyspepsia any confusion or equivocation sufficient to account for its indefinite use? It was almost trivial to remark that dyspepsia was not a disease, but a symptom. But used in this sense, its meaning was almost futile, as futile as it would be to apply the term dyskinesis to all the different forms of difficulty, unsteadiness, or pain in walking, and to treat them under that heading in a single chapter. And yet we had only to turn to any modern text-book to find pages devoted to the symptom of dyspepsia, that which is accidental and consequent being raised to the place and name of a definite malady. It was necessary to clear away this confusion, and to set out as distinctly as possible in their natural groups the several classes now heaped unreasonably together. Perhaps by this method we might succeed in reducing the word dyspepsia to an indefinite connotation, such as that of the word cough, which signified only an inconvenient and notorious symptom, common to many maladies.

The four chief groups of stomach disorder attended with dyspepsia were :—

1. Those due to grave disease of the stomach itself—cancer, ulcer, dilatation, &c.
2. Less grave diseases of the stomach, as the simpler catarrhs, acute and chronic gastritis.
3. Disorders depending on no visible structural change, but consisting in some disorder of the work or secretions of the stomach—functional disorders.
4. Disorders depending on some influence coming from blood or nerve, from which influence visible local changes may or may not ensue.

He would dismiss the disorders of the first class, and those of the second class also, so far as they could be distinguished. Between these cases and those obviously neuralgic, there were a number of cases which it was difficult to classify, it being difficult to decide whether the stomach derangement was an expression of some general derangement, or a substantial ailment and the cause rather than the consequence of any more general perturbation. And there were cases, still more difficult to interpret, in which dyspeptic symptoms were no doubt due to disordered work or secretion in the stomach, though that in its turn might be due, not to any primary defect in the organ, but to some cause lying outside it in the first instance, perhaps in the nervous system. A sudden nervous shock might completely arrest digestion, and it was conceivable that lesser degrees of nervous perturbation might keep up a continual dyspepsia. Then there were cases in which patients, suffering from other symptoms of nervous derangement, complained of the gathering of a dense yellowish oily fluid in the stomach every morning, which, if not moved by vomiting, would act as a foul ferment on all food subsequently introduced. This symptom he believed to be due to some perturbed innervation of an otherwise healthy stomach, and it was curable by treatment planned mainly upon that diagnosis. A further difficulty in these cases was, that the process might be reversed, and a slight catarrh or some graver local mischief might set up nerve perturbations, which would overshadow and conceal the primary cause of their occurrence. Thus, in some cases, the diagnosis between ulcerous and simple gastralgia was in certain stages impossible. Often, however, that which reason and examination failed to discern might be revealed by the test of treatment. In order not to fall short of a rational therapy, it was necessary to see with some clearness, how the pure neuroses of central origin were related to the nervous phenomena awakened by pre-existent or foregone local maladies. Advancing from the simplest cases to the more complex, he would first consider those in which disorders of digestion occur, as a consequence of general nervous exhaustion. Such cases might occur in men and women of very various habit of body, and the symptoms were various. He found two kinds of dyspepsia in persons over-worked. In the one, the tongue was clean, not red, but pallid, œdematous, and with indented edges. The patient had no appetite, and the little he ate caused a weary sense of repletion. In the other class of cases, the tongue was bulky and also indented, protruded slowly, and spreading forth as it issued. It was thickly coated, especially towards the mid-line and back, with a brownish fur. The complexion was muddy, and the countenance depressed, and there was pain, or an indescribable uneasiness at the vertex and round the occiput. A like state of tongue, and a like sluggishness of stomach, liver and colon might be seen in apoplexy, and were then clearly secondary to the troubling of the brain, though the converse was usually held. All attempts in these cases to clean the tongue and set the stomach right with the stock rhubarb and soda mixtures, with pepsines, with calomel, colocynth, or colchicum, met with disappointment. Strong tonics, such as quinine, might be prescribed with benefit, but rest and upland air would beat all medicines. Here the disorder of stomach was due to a neurosis, vascular or other, and curable only on that understanding.

The lecturer then proceeded to illustrate his contention by illustrations taken from other viscera. Jaundice, constipation and diarrhœa, he said, might be due to nervous causes acting alone, to local causes acting alone, or to local changes reinforced by nervous changes. The uterus, again, had its maladies of local causation, its maladies of nervous causation, and its maladies of mixed causation, and to assume that all uterine neuroses were due to coarse changes in the womb itself was as dull as to suppose that the face could never be the seat of tic unless there were decayed teeth in the jaw. He did not doubt that a very large number of uterine disorders, which were elevated to the place and name of diseases of the uterine system, were but manifestations of neuroses, for all neuroses were commoner in women than in men. On the other hand, it was equally unjustifiable to put down all abdominal pain in women as hysterical.

"A neuralgic woman," said Dr. Allbutt, "seems to me to be peculiarly unfortunate. However bitter and repeated may be her visceral neuralgias, she is either told she is hysterical or that it is all uterus. In the first case she is comparatively fortunate, for she is only slighted; in the second case she is entangled in the net of the gynæcologist, who finds her uterus, like her nose, is a little on one side, or again like that organ is running a little, or it is as flabby as her biceps, so that the unhappy viscus is impaled upon a stem, or perched upon a prop, or is painted with carbolic acid every week in the year except during the long vacation when the gynæcologist is grouse shooting or salmon catching, or leading the fashion in the Upper Engadine. Her mind thus fastened to a more or less nasty mystery, becomes newly apprehensive and physically introspective, and the morbid chains are rivetted more strongly than ever. Arraign the uterus and you fix in the woman the arrow of hypochondria, it may be for life."

It was time, continued the lecturer, that the reaction from this gynæcological tyranny was completed. No man, it was true, limited by the bounds of human intelligence, could possess a fine knowledge of medicine, surgery, and obstetrics, but every man could and must have a good all-round knowledge such as would enable him to take the main bearings of any case which might come to him. For his part, no convention arrested him

from using the speculum and uterine sound, when required for diagnosis. This done, he was able to judge under whose care a patient might best be placed. He repeated that the main lines of the diagnosis of any malady whatsoever should be within the province and abilities of any medical man whatsoever. The physicians had been feeble folk in bearing the taunts of the gynæcologists, whose stories of long pain and sickness uncured by medical futilities, but rapidly cured under uterine medication, could be checked and even mated by double the number of cases rescued by the physician from the sofa, the manipulations, and the mental abasements of uterine specialism. The wisest and most disinterested of gynæcologists now knew how narrow had been the views, and how deceptive the data which had passed current in their school, and they were ready to declare that they must share the culture of a great part of their field with the physicians. The latter had been at least as much to blame, in having committed the central blunder of stupidly confusing between the hysteric and the neurotic subject. A hysterical person was one of feeble purpose, of limited reason, of wilful impulse, of irregular or depressed appetites, of indefinite and inconsistent complaints; or, when hysterical in a lesser degree, was capricious, listless, wistful, attractive, yet having always the chief notes of hysteria—selfishness, and feebleness of purpose. Such a person was no doubt a member, a degenerate member, of the neurotic family, but her adjective ought not to be applied to the neuralgic members of the group, who were often rarely endowed with capacity, endurance, and imagination, forming a large number of those in the second rank who are the salt of society. The typical neurotic man was described by the lecturer as active and slightly built, meagre and mostly of sallow complexion, with hollow cheeks and temples; the hair straight, fair, and sparse, the features sharp, lips thin, and skin dry. The tongue was generally narrow and pointed, with often a light silvery coating on the dorsum. The pulse when most tranquil ranged between 70 and 80, and the heart's apex might be seen and heard to beat sharply. The conversation of such a person was lively and voluble, often keen and brilliant. He was subject to great fluctuations of spirits, being gay in society and brisk in business, but dejected and fretful at home. Such a patient was the heir of every true neurosis from insanity to toothache. If a woman, she was liable to uterine and ovarian neuralgias and hyperæsthesias. The neurotic woman ought not to be called hysterical. She was sensitive, zealous, managing, self-forgetful; while the hysterical woman was languid, purposeless, introspective and selfish. Of the flock of women who lay under the wand of the gynæcologist, a preponderating number were neurotic, and their uterine and ovarian disorders were either wholly neurotic or so reinforced by neurosis as to depend chiefly upon general medicine.

Dr. Allbutt then gave details of an illustrative case, in which a neurotic young lady who had suffered from uterine neuralgia and concomitant dysmenorrhœa and leucorrhœa, and who had been treated locally for a year or two, was entirely cured by general treatment. The case, he thought, was one which could be multiplied a hundredfold; it was one of the class of cases which form the greater part of those which are caged up in London back drawing-rooms, and visited almost daily for uterine disease. He asserted that, in neurotic subjects, uterine laxities, moderate displacements and catarrhs owed their continuance, and often their very initiation to an atonic state of body, and to a special instability of nerve which might show itself in local trophic changes and in perverted secretions. To attempt to cure such a malady by local means, was as wise as to try to cure a syphilis by antiseptic dressing of its ulcers. This was well known by our more robust, more clear-sighted and more true gynæcologists; but others, with their reason bounded by the confines of the pelvis, attempted to stem the tides of general and diathetic maladies, with little Partington mops of cotton wool on the ends of little sticks. Later on he would recall the truth which should be ever before us, that the fundamental difficulty in all neurotics, not hysterics, was their nutrition.

"A shrewd old Yorkshire doctor once said to me," Dr. Allbutt observed in conclusion, "'It's no use, my lad, putting the hands right upon the clock face, if you have not cleaned the works.' Gentlemen, we are all one-sided. I speak to-day from my own one-sidedness, and my convictions are upon the side of cleaning and repairing the works. Sometimes, no doubt, when the general state of the health is restored, some local trouble, set up originally by the constitutional state—be it gout, scrofula, or what not, smoulders on, forgotten as it were, after the general malady is cured. For such local trouble, diathetic treatment no longer avails, it must be wiped out by some local alterative, but on the other hand, to contend daily with local troubles which daily are regenerated by some vicious habit of the whole system is to roll up daily the shameless stone of Sisyphus."

Lecture II.—[Abstract.]

After commenting on the fact that gastralgia, one of the sharpest arrows in the armoury of pain, was so briefly dismissed in many medical works as a malady of "hysterical women," the lecturer said that this symptom was common enough in men also. It was the chief of all the neuroses of the stomach, but around it gathered, in more or less close association, flatulence, vomiting, hyperæsthesia, and miseries such as distension, sinkings, cravings, and loathings of food. As in angina pectoris and pseudo-angina, so in gastralgia the spinal nerves might be included in the paroxysms, as well as the visceral nerves. Taking the ten years from 1874 to 1883, he found in his case-books that he had reliable notes of 139 cases of gastric and abdominal neuralgias, after all doubtful and trivial cases, all cases complicated with substantial disorder of the uterus or other organ, and all hysterical cases had been eliminated. These patients were subject to neurotic or neuralgic affections lying under the diaphragm and above the pelvis, mostly gastralgias. The majority of these gastralgics were women, in the ratio of two to one. The affection occurred at all ages from fourteen to sixty, being most common from twenty to forty-five, and tending like migraine to die out in middle life. It came on earlier in woman than in man, apparently by some ten years. In fully 80 per cent. of the cases it was associated with migraine or neuralgia of face or head, the two affections alternating. Other disorders associated with gastralgia were asthma and palpitation; attacks of slow or intermittent pulse formed another characteristic symptom. In a lady who suffered from marked gastralgia, attacks of dull prolonged pain in the region of the heart and under the left shoulder blade, with very slow (48 to 50), intermittent and irregular pulse, were brought on at once by putting her child to the breast, even before any milk was withdrawn. In another case, a male, aged 37, liable to violent attacks of gastralgia, suffered also, though less frequently, from "heart spasms," in which the pulse became much enfeebled, and, according to his doctor's account, was slowed down as low as twenty in the minute. Physical exertion did not bring on the attacks, and there was no organic fault. A lady, aged 33, suffered, especially after fatigue or abbreviated sleep, from intense aching at the heart, coming on at four or five p.m.; she had to lie down and "press the heart." She was subject also to gastralgia. Another lady, aged 43, subject to severe menorrhagia, but free from

persistent affection of the womb, suffered occasionally from gastralgia, and also from attacks of stabbing pain at the apex of the heart, intense cardiac oppression, and all the symptoms of angina pectoris.

Diagnosis in these cases depended less on the character of the attacks, than on the other records. The attacks were commonly due to such losses as menorrhagia or severe leucorrhœa, or to prolonged mental distress, and were not directly produced by bodily exertion. The pains in some cases were more extensive than was usual in angina. About twenty per cent. of the cases occurred in men. In a gentleman of neurotic habit, attacks with marked signs of true angina diminished and entirely ceased as his fortunes mended. The tendency to retardation of pulse apparently brought these cases into the group of vagus neuroses, with asthma and gastralgia. The phenomena of pain and spasm were probably due to the pneumogastric nerve and the intercostal and spinal nerves associated with it, while the faintness, sinking, distension, palpitation, abdominal pulsations, flatulence, retching and vomiting, pyrosis, diarrhœa, and so forth, might be attributed to the sympathetic alliances. As well as pseudo-angina, cervico-brachial and intercostal pains were found with gastralgia. A lady, a sufferer from severe gastralgia, had nocturnal attacks of pain down the left arm, which felt quite benumbed and useless. Another lady had ordinary gastralgia, attended with pain running into the left sub-mammary and axillary regions, and into the left arm. At the beginning of her attacks she passed urine frequently. Another lady, subject to migraine and cephalalgia for years, was also subject to attacks "pinning the shoulders tight," and girdling her with pain round the waist, which almost stopped the breathing; after some hours she vomited, and the pain departed. In a similar case in a man the attacks culminated, not in vomiting, but in diarrhœa. Another curious symptom which occasionally came with gastralgia was yawning.

In some cases of gastralgia vomiting took a very prominent place, and was sometimes difficult to distinguish from the vomiting of migraine. The latter, however, commonly occurred in the morning, was more periodic and at longer intervals, while the vomiting of gastralgia was irregular in its occurrence, and more dependent on the ingestion of food. The vomiting of migraine might occur without headache, as that of gastralgia might occur without stomach-ache, and illustrative cases of this were quoted. One lady, after suffering from migraine for nine years, lost her headaches, but still suffered from attacks of vomiting, during which she had to keep as quiet as if she had a sick headache. She was a type of the more highly endowed neurotic, and was much benefited on economising her strength, and resting at times of *malaise*. Another lady, equally free from functional derangement, had very similar symptoms. Both cases derived much benefit from a mixture of bromides and hypophosphites. Several cases were quoted as examples of vomiting associated with gastralgia. A male, aged 50, had been liable all his life to sick headaches, alternating with gastric attacks, also attended with vomiting. For two years past his trouble had mainly been vomiting in the morning, a little phlegm only being ejected; at such times he was unable to retain food until dinner time. This appears to have been gastralgic vomiting, and he was cured by a course of bromide of ammonium with hydrocyanic acid, followed by a course of Easton's syrup.

It was somewhat remarkable, continued Dr. Allbutt, that though migraine and gastralgia very commonly arose in the same patient, and though both were often attended with vomiting, yet they seldom or never occurred together. He suspected, therefore, that the vomiting of migraine was not identical in mode with that of gastralgia. In the latter it might be reflex, in the former it might be allied to the vomiting of encephalic tumour and of concussion. Cases in illustration of this were quoted; one was that of a male, aged 23, who woke every morning with depression, nausea and loss of appetite, and after free vomiting of nothing was all right; he was cured by guarana, and was thought by the lecturer to be a case of migraine *sine cephalalgiâ*. In another case, a lady, aged 35, there was the same nausea and vomiting in the morning, worse especially when she was much below par; she also expelled a great deal of wind, clear water ran from her mouth, and there was at the same time pain between the shoulders; the patient had a soft uterus, and suffered from intense supra-orbital neuralgia; in this case the stomach was at fault. A third case carried us a step farther. A lady, aged 41, suffered from languor, followed by intense pain at the stomach, and vomiting of clear water only; the attacks sometimes recurred as often as four times in 24 hours, and were often attended with a "screwing" pain in the back; not infrequently she had the vomiting without any pain. These last two cases would lead us to believe that pyrosis for the most part is a gastric neurosis, and it would be found that the subjects of it belonged to the neurotic class. Regurgitation was also, in some cases, a purely reflex neurosis, and not always due to an error in digestion. A case was quoted in which a young man constantly suffered from this symptom, without any evidence whatever of dyspepsia. He was attacked by facial neuralgia, and the regurgitation at once ceased, and had not recurred. This symptom was doubtless due to an irritability of the muscular walls of the stomach, setting up excessive contraction under the stimulus of digestion. Another form of vomiting had to be considered—vomiting on the full stomach. This terrible malady had been but ill discriminated, being mixed up with hysterical and uterine vomiting. The former was curable by uterine treatment, and hysterical vomiting was consistent with fatness, whereas gastralgic emesis led straightly to emaciation. It came on with or without pain, but in both cases the cause was cognate if not identical. Dr. Salter had recorded a case in which this affection had alternated with spasmodic asthma. It was distressing to hear of such cases being treated almost with gibes as hysterical. Happily they were not common. The malady might properly be called gastralgic vomiting, seeing that the mode was the same as in the cases wherein pain was also a factor. For instance, in one case painless vomiting followed the meals, and severe gastralgia of the ordinary type came on in nocturnal seizures after the manner of its cousin, asthma. In another case, a young lady, after being subject to facial neuralgia, was attacked by gastralgia after eating; this pain vanished and she became subject to gastralgia on the empty stomach only. This in its turn disappeared and vomiting set in, all food being ejected; she made a good recovery on arsenic. These cases led up to those which similated gastric ulcer, and in which diagnosis was almost impossible. They occurred in young women, and were marked by the sequence of ingestion of food, severe pain in the stomach, vomiting and relief; and if this was accompanied by the vomiting of blood, the diagnosis of ulcer became almost inevitable, and yet, according to the correctness of our judgment, must our treatment be helpful or positively mischievous. The two classes of cases, ulcerous and pseudo-ulcerous, were about equally common; emaciation was perhaps rather more usual in the latter than in the former, but a safe diagnosis was best reached by a careful review of the patient's life-history, diathesis and associated symptoms, the discovery of neurotic antecedents often helping us.

The lecturer then passed on to consider hyperæsthesia of the stomach, which he said was not always or

even generally associated with vomiting. The state much resembled the irritable uterus of Gooch and the irritable spine of Teale and the Griffins, all of which maladies, though often coincident with hysteria, were, nevertheless, essentially independent of it, and occurred also in the higher class of neurotics. Irritable stomach was a grim reality in many cases, though hyperæsthesias and anæsthesias as functional disorders no doubt belonged also to the hysterical class, and it might often be hard to say, in a given case, where active neurosis ended and where a brooding persuasion of pain began.

Dealing with the *anorexia nervosa*, cases which have been published by Laségue and Sir William Gull, the lecturer said that it was no whimsical malady but a definite complex, consisting in part of objective symptoms. It occurred in young women who inherited a decided neurotic taint, and five objective symptoms were always present—namely, amenorrhœa, constipation, sub-normal temperature, slow pulse, and cold extremities, all observable long before they would appear as simple results of inanition. In some cases the pain which followed the use of food was agonising, but in most the pain was absent or insignificant, and there was simply an invincible distaste for food. He had not found vomiting present in the majority of cases. Hyperæsthesia of the stomach might be met with in anorexia nervosa, and then it was a grievous addition. Such cases were constantly confounded with dyspepsia. A solicitor, aged 31, complained of "grievous indigestion," pain coming on soon after meals, and lasting from one to two hours; his tongue was quite clean, his secretions normal, and he had no offensive flatulence. All food gave him pain alike, but fatigue or annoyance increased his liability to the torment. He had previously had severe neuralgia in the head, and a well-marked but brief attack of melancholia, and his family history was neurotic. He was cured by Easton's syrup. But the diagnosis was not always so easy, and cases were quoted in illustration of this. In one case, a lady, aged 22, who suffered from intense pain after food, with vomiting and consequent relief, was greatly benefited by warmth, a result worthy of pointed reference, as such treatment would not probably relieve the pain of ulcer. It must be remembered, however, that in organic disease of the stomach the pain might be independent of food, and thus closely simulate simple gastralgia.

There yet remained a very characteristic symptom of gastralgia, viz., flatulence, which in typical cases was a portentous thing. It might concur with pain, or come on independently of it. That it was of other origin than the mal-digestion of food, was, he thought, imperfectly realised by the profession at large, though this, in striking cases, was obvious. It recurred often with the same periodicity as gastralgia itself, and, like it, had a fondness for the small hours of the afternoon, or of the early morning. "The patient wakes, let us say, at two or three a.m., with a sense of distension which he knows but too well. His body is sometimes flat, but more often has swelled about the epigastric region, and become tight and hard. For a while restless and distressful, he rolls upon his face and rubs his belly until 'the wind begins to move.' This, as it does so, rumbles upwards rather than downwards, and delivers itself by no common eructation, but the working load rises in a series of eruptions, which roll from the throat in successive waves of flatuosity. It is a prolonged storm rather than an explosion, and its tumult will keep the patient raised in bed, heaving in strife with it for an hour or two before he finds ease." Several illustrative cases were detailed, amongst them the following: — A solicitor, aged 30, had been very hard-worked. First came dull heavy pain in the left side. Then he became subject to "painful distensions of the body, not by food," and extreme flatulence. With this came a great dyspnœa like spasmodic asthma, or again dizziness so severe that he feared he might fall. He passed profuse and pale urine at such times, and if a woman he would have been written down a hysteric; whereas he was a man of intellect and good sense, and held successfully a high professional position. The only difficulty in his case was to secure for him a sufficient rest. It was to be noted that in all these cases the wind was quite inoffensive. Whether it were carbonic acid, common air, hydrogen, or what else, he was unable to say, as he had never tested it. By its mode of occurrence, the suddenness and volume of its generation, as well as in its innocence of taste or odour, it was clearly marked off from the foul wind generated by the fermentation of food. It was certainly produced in some way by the agency of the nervous system.

A further symptom of gastralgia was distension of the body, real or false. It was often unassociated with any consciousness of the presence of flatulence, and, moreover, was not confined to the region of the stomach. He had already referred to the horrible deathlike sinkings which belonged to gastralgia, though not always actually coincident with the pain. A male, aged 28, after a few months worry, began to have neuralgic pain in the left arm and up the neck. After this he became subject to nocturnal attacks of "want"—not a craving, nor exactly a faintness, but "an awful emptiness, with a dread at the heart." He was substantially quite healthy, and was soon cured on restorative and tonic treatment. Slighter degrees of this distress often accompanied gastralgia or enteralgia, or with an unaccountable languor preceded them. These subjective sensations were, of course, to be distinguished from the collapse, sometimes alarming in its degree, which was consequent upon the intenser attacks of abdominal neuralgia. The intensity, indeed, of most severe cases of gastro-enteralgia might be seen in the ashen cold face and blue nails. Finally, most gastralgics were subject, not when actually suffering only, but also at all times, to borborygmi. Few people were ignorant of this phenomenon, but it was in neurotics especially that they reached their most lively and garrulous forms. An old and valued domestic, who had lately retired, after twenty-five years of household service, and who presented all the phenomena of gastralgia in an active form, was so embarrassed by these audible internal questionings that she almost withdrew herself from waiting at table. Tonic measures and gentle dumb-bell exercises were most potent to remove this disorder.

CASE OF SYPHILIS IN WHICH THE FINGERS OF ONE HAND BECAME COLD AND LIVID—SUSPECTED ARTERITIS.

By JONATHAN HUTCHINSON, F.R.S.,
Consulting Surgeon to the London Hospital and to Moorfields, and to the Hospital for Skin Diseases, Blackfriars.

THE case which I am about to narrate was under my observation nearly twenty years ago. I have abstained from publishing it — although, in my experience, almost unique—because I was quite unable to offer any satisfactory conjecture as regards diagnosis. It seemed possible that other cases might occur which would throw light upon it. None such have, however, come under my notice, although, as will be explained subsequently, there are certain facts of a less definite character, which may not improbably be allied in real nature. It was only the other day on reading over the notes again, that it occurred to me that the cause of

the symptoms must have been inflammatory occlusion of the arteries of the hand. At the time the case was under care, this diagnosis never crossed my mind, and consequently I failed to investigate certain points which might have confirmed or refuted it, chief amongst these being of course the state of the digital vessels, and of the ulnar artery. In reviewing the case, I confess that it seems strange that this investigation was overlooked, but at the time, my mind was pre-occupied by the hypothesis of nerve cause, to which the very severe pain seemed to point, my notes state that the radial pulse was (at one date of observation) not materially weaker than that of the other wrist, but it will be seen that the symptoms were more marked on the ulnar side. It is, besides, very possible that the arteritis, if such there were, began peripherally, and travelled upwards. Possibly it never reached the larger trunks.

It is in part the impossibility of explaining the symptoms on any nerve hypothesis, which induces me now to resort to that of local arterial occlusion. The fingers affected were not those supplied exclusively by any one of the nerve trunks of the forearm, and there was never any loss of sensation, or of motor power, nor were the local changes such as those which we recognise as common in any form of paralysis. They were lividity, coldness and pain: for the most part indicative rather of disturbance of nutrition and circulation, than of nervous influence. A certain school of observers will probably claim the case as an instance of disease of the vaso-motor system, but in reply to that, I must allege that we know nothing of the occurrence of such symptoms as were here present, in cases in which the ganglia or trunks of the sympathetic have been proved to be involved in disease, or destroyed by injury. I will defer till the conclusion of my narrative the statement of certain other facts which seem to give further support to my diagnosis. The facts recorded in the following notes are given precisely as they were written out, without any theory in view, at the time the case occurred.

Mr. C., aged about 30, was sent to me in April, 1864, by Dr. T. Wright, under whose care he had been at Nottingham. He was known to the subject of constitutional syphilis, and was believed to be suffering also from phthisis. As he was losing flesh, and occasionally spitting blood, it had been felt to be difficult to recommend a continuance of mercurial treatment. On his thighs and trunk were large patches of superficial serpiginous ulceration of undoubted character. From these he had suffered with some temporary alleviations for a year past. About four years ago he had passed through primary syphilis, followed by the usual secondary phenomena. He had several times taken mercury, but never to full salivation. With regard to his chest malady, I requested the advantage of consultation with Dr. Peacock, who, after careful examination, gave the opinion that there did exist undoubted tubercular deposit to a slight extent in the left apex. We advised our patient to spend a few months at different bathing places on the south coast, to live liberally as regards meat diet, and to take specific remedies. The medicine which I prescribed, consisted of ten grains of iodide of potassium, a drachm of the solution of the bichloride of mercury, and a drachm of sal volatile, in one dose, three times a day.

Mr. C. came to me once a fortnight, during the next three months, and as he was steadily gaining ground in all respects, I made no material alteration in the plan of treatment. On June 21st, he returned home, having then for some weeks been quite well of the eruption, and being in much improved general health. He looked strong, and had gained flesh, and lost his cough. At this date, however, he mentioned to me for the first time, a symptom which subsequently became of great interest. It was a constant aching pain in the middle finger of his left hand. There was little or nothing to be seen, and I paid little attention to it, but advised him to use some iodine ointment. He had taken the medicine regularly whilst away, but latterly we had omitted the mercurial, and substituted three grains of the bromide of potassium for it. I now ordered a smaller dose of the iodide to be taken only once a day.

During the next two months Mr. C. remained at home, and enjoyed good general health without any relapse of the eruption. The pain in his middle finger, however, got worse, and after a while, the other fingers were involved also. Various measures were tried by Dr. Wright for his relief, but without much benefit. In September, Mr. C. wrote to me about his hand, and on October 1st, he came up to town to let me see it. It presented a most peculiar condition. The fingers were blue and mottled, as if they had been exposed to great cold, this condition, being most marked at their ends, and diminishing gradually towards the knuckles. The middle finger which had been first affected, was now almost well, and the thumb had never suffered much. On touching the fingers I was struck with their great coldness, and on using the thermometer we found that there was ten degrees difference between corresponding parts of the little, middle, and ring fingers, (near their ends), of the two hands. It was a fine warm morning, and the affected hand had been in a glove, whilst the other had been exposed, so that there was no room for fallacy on this score. The ends of the left fingers mentioned, averaged about 76°, whilst those of the right hand were 86°. On trying the cleft between the middle and fore fingers of the two hands, I found the left 91°, whilst the right was 92°.

The following memoranda were taken at the time:—

"The thumb is quite warm, it is sometimes a little mottled, but never so much as the others.

"The middle finger is warm and less painful than the others.

"The fore-finger, ring-finger, and little finger, are those chiefly affected. They are blue and mottled, and at their pulps are quite livid. On the ring-finger, at its pulp, there is a troublesome sore. It consists of a a sub-cuticular suppuration with livid edges. It is very tender, but in all other respects resembles those which I have seen on fingers after section of nerve trunks. He describes the pain as "an aching smart." It is almost constantly present, indeed, for the last month it has never once been wholly absent. A month ago, for one day, the fingers were suddenly, and without apparent cause, free from pain. It returned the next day. It is severe at nights, and often keeps him awake, he rarely sleeps more than an hour or two at a time. The nails are quite livid. The palm of the hand frequently perspires very much. It is at present covered with drops of sweat. He has no headache, and feels well, if only his hand were free from pain. The sores have not relapsed, and he has now no cough or expectoration. He mentions a curious sensation of tightness about the left eyelids, which he often feels. His pupils are of equal size, and his sight and accommodation-faculty perfect in both eyes. The ring-finger was the last to suffer, and is now the worst. The middle finger is now almost well. He does not feel any numbness in the fingers, and there is no anæsthesia of the skin discoverable by the compasses. The inflamed finger is very tender to the touch. He states that sometimes there is a feeling of muscular weakness in the hand and forearm, as if he could not move the fingers. They are so stiff, although very little swollen, that he cannot flex them much. The whole arm is flabby and thin, considerably thinner than its fellow."

At the date of the preceding notes I carefully examined both arms, and had his chest stripped. The pulse at the left wrist was nearly as strong as that at the right, and there was no evidence of occlusion of veins. The ulnar nerve could be easily felt at each elbow, and was not enlarged on the affected side. He complained that it much more easily caused pain and tingling when it was pressed on the affected side, than on the other. This was the only difference. I could not discover any evidence of aneurysm in the neck or chest.

Six months after the pain had ceased, I had an opportunity for again examining the hand. The temperature of the ring-fingers of the two hands was now the same, 93°. He had been walking and the morning was close. The affected fingers were much thinner than those of the other hand. The nails, owing to the shrinking of the fingers, were much more curved than those of the other hand, but there was no clubbing of the finger ends. The treatment throughout had been by specifics.

Mr. C. lived some years after these notes were taken; and, finally died of acute abdominal mischief. He had experienced no further trouble from his syphilis, nor any return of the pain in his fingers.

It will be seen that although the finger tips never actually went into gangrene, they were very near it. The disease was of a slowly aggressive character, and affected one finger for months before the others were involved. The attack lasted altogether nearly six months. It differs much from the cases described by Raynaud, under the name of peripheral asphyxia, inasmuch as it did not involve all the digits and was marked by extreme pain. Since its occurrence I have seen several cases favouring the belief that arteritis may begin in the small peripheral vessels, and may travel to larger trunks. If in this instance it began in the vessels of the middle finger, and spread upwards and involved the superficial palmar arch, the phenomena might be fairly well accounted for. The interesting case brought by Mr. Pearce Gould before the Clinical Society a few weeks ago, was possibly a parallel to it, excepting that it was much more severe. In it progressive occlusion of the brachial (travelling upwards) was proved, and most of the finger tips at length sloughed. Whether in my case syphilis was the cause, may be open to some doubt, since the patient had been for some months under efficient specific treatment, and was just well of all other symptoms.

CASES OF SPINAL DISEASE, ILLUSTRATING THE CLINICAL HISTORY OF SPINAL SCLEROSIS.

By JAS. RUSSELL, M.D., F.R.C.P.,
Physician to the Birmingham General Hospital.

(*Continued from page* 280.)

A Case of Infantile Paralysis in the Adult; and a Case of Amyotrophic Lateral Sclerosis (Charcot).

I have brought the two following cases together, because they exhibit between themselves a contrast possessing much pathological interest, and which, sufficiently striking of itself, derives additional importance from an opinion of M. Charcot; an opinion which regards the cases, to which my second case belongs, as constituting of themselves a distinct group of the remarkable class of spasmodic spinal pareses, a group to which he has applied the title quoted at the head of this paper.

As to my first case, it is a very typical instance of a disease, well recognised of late, in which what used to be known as infantile paralysis presents itself in the adult individual.

Referring now to the comparison between the two cases, in each case paresis with atrophy of muscles is the leading symptom throughout, and gives to the case its characteristic aspect; there is loss of muscular power and atrophy, even destructive atrophy, of muscular tissue. In the case of so-called infantile paralysis, whether in the child or in the adult, this condition of paresis and atrophy comprises the essence of the malady.

In amyotrophic lateral sclerosis, on the other hand, the muscular atrophy is but a part—a very important part—of the case; a spasmodic element is superadded; and thus the disease holds out a hand, on the one side, to the spasmodic paresis which has been the subject of the foregoing illustrations, whilst retaining marked individuality through the muscular atrophy which is still its most prominent symptom. In my patient, the atrophy will be seen to be very marked, even more than in the case of infantile paralysis, though by the superaddition of other elements, standing broadly aside.

This group of spinal amyotrophies was described at length by M. Charcot, in his well-known "Leçons"—2me partie, douzième leçon et seq.—and a further explanation of the author's views is given in an appendix to the New Sydenham Society's volume, already referred to; in which, moreover, a controversy is conducted with the opposing view of M. Leyden.

There are other features, besides the spasmodic element, which are regarded by Charcot as adding to the individuality of the group of amyotrophic lateral sclerosis. My case illustrates these features. In the present instance the spasmodic element is less pronounced than in the typical cases; it is, however, declared in the clonos of the lower extremities, and also in the tendon phenomena, which are regarded by M. Charcot as themselves an exposition of the spasmodic element. An important feature in the typical disease picture, is the early extension of the atrophic process to the motor cells of the medulla oblongata, whereby the symptoms of bulbar paralysis are added to the other phenomena of the case, modified, however, by intermixture with a spasmodic development; in my patient these symptoms were in an early stage, having apparently been delayed (according to the course usually described), the spasmodic part being simply illustrated by morbid irritability of the palatine muscles. Another special characteristic is the decided predominance, in point of time, of the paresis over the wasting; this predominance is illustrated in the subject of the present case, by a marked peculiarity appertaining to these cases; the lower extremities are in a condition of advanced paresis, whilst the nutrition of the muscles is maintained, and even a considerable amount of Faradic contractility. This difference between the upper and the lower extremities is regarded as very important; it is certainly very striking; and it continues till the closing period of the case.

In the chronic form of muscular atrophy, the ordinary "progressive muscular atrophy," the wasting process proceeds by individual muscles, occupying, it may be, even twenty years in its complete course; in the acute form the whole system of motor cells is sometimes overwhelmed at once. In the amyotrophic lateral sclerosis the disease proceeds by groups of muscles, answering, no doubt, to the separate collections of motor cells, functionally banded together; the degree of rapidity with which the atrophic process is conducted, approaches much more nearly to the acute form, that of infantile paralysis, than to the long-delayed progressive muscular atrophy. Moreover, so far as yet appears, the tendency is steadily to death. The atrophy advances

LIVERPOOL MEDICAL INSTITUTE

with no slow steps, but it is the bulbar affection which usually determines the fatal termination.

The exact limits of my patient's illness are not clearly defined; but the advance of the symptoms under our observation renders it probable that the duration may not exceed the short term of three years, usually observed in these patients.

With reference to my first case, I may say that the earliest public description of infantile paralysis occurring in the adult is given in Duchenne's work ("De l'Electrisation localisée"), 2me partie, in article i., chapter iii., "Paralysie spinale anterieure aigue de l'Adulte;" though it appears, from a series of articles in *Le Progrès Médical*, 1874, that M. Kussmaul had noticed the distinguishing character of the disease in 1865. A lecture on the subject was given by M. Charcot in 1870, and later observations, 1874, are contained in his "Leçons." Since that time M. Charcot's prophecy that the malady would be found of more common occurrence than had been supposed, has been verified.

My case presents an excellent illustration. The whole four limbs were implicated, and, contrary to what often happens, all the muscles affected have probably recovered. The disease commenced suddenly, as is usual. In *Le Progrès Médical* are some interesting examples of the sudden manner in which the paralysis sometimes makes its appearance: in one patient, aged 60, in half-an-hour from invasion all movement was impracticable; another patient, who had gone down into the open court from his bed, thinly clad, with naked feet in his slippers, whilst in a state of perspiration, found he could not handle the soap on regaining his room, and next day was unable to pay for a cab, because he could not handle his money.

With respect to the period which may elapse before motor power is regained, in one of the cases just referred to, the patient began to recover power, after two years passed in absolute immobility; but recovery was very incomplete. In my patient recovery began early, and when he passed from our observation, promised to be complete.

Case I.—Infantile Paralysis in the Adult.

Mrs. A., aged 28. She made the following curious statement:—When fourteen years old she was exposed to white lead poisoning, at some porcelain works; at the end of two months she became seriously ill and lost flesh: the doctor told her she was suffering from lead poisoning. She left the place at once and never had any other symptoms of plumbism. There is still a thin blue line along the edge of the gums. She reports protracted diarrhœa for a year before her present attack, which began eight weeks ago with a "fit," which left her unconscious for an hour. At the end of a week her hands, and in two days her legs lost power, and were numbed; in each case the paralysis was complete in three days. A sharp pain shot up the legs from the toes and the middle of the feet, and this pain existed at her admission. There was no important trouble with bladder or rectum; nor with the special senses. Menstruation had been suspended for ten months; it reappeared during her recovery. Her health was unaffected; she was a large, stout, flabby woman. There is absolutely nothing else to notice in her history; nor anything to indicate a cause, unless it be the remote poisoning with lead. On admission we found the muscles of the four extremities paralysed, and hanging loose and flabby; the muscles swaying to any impulse; this was the case, however, in the legs to a less extent than in the arms, and the paralysis was less complete. The deltoids were partially wasted; the shoulders were raised by the trapezii only. The only knee phenomenon was an occasional slow contraction of the muscles of the thighs when the patellar tendon was placed on the stretch. The plantar reflexes were active, and became abnormally so. The points of the compasses were distinguished in the fingers at three-quarters of an inch. Some Faradic contractility was preserved in the right forearm alone; slight contraction on cathodal closure, 40 cells, took place in the flexors of the right hand. Any sign of the reaction of degeneration was everywhere entirely absent.

Uterus and rectum were healthy (Dr. Malins). A myopic crescent was the only abnormal appearance in the fundus oculi (Mr. Priestley Smith).

She remained in the hospital from April 14th, 1883, till January 5th, 1884, when all her muscles appeared to have regained their function. The treatment depended chiefly on the assiduous use of the hot mustard bath, to all four limbs, and manipulation of the muscles. Galvanism, at first Faradism (for the sake of convenience), afterwards by the battery current, was assiduously employed. Probably the recovery of the larger muscles would have taken place unaided; but there could be no question of the efficacy of the current in saving the small muscles, which, at one time, were seriously threatened, and which relapsed at each intermission of the battery. Liquor strychniæ was administered, but never in above three minim doses. One blister was applied to the vertebral region.

During the process of recovery, which occupied nine months, the lower extremities took the lead; the muscles of the shoulder and those of the elbow and wrist, preceded those of the hand and thumb; the thenar muscles were at one time seriously threatened. The last muscle to recover was the long extensor of the right thumb.

I watched with some interest the process of recovery. It may be briefly stated as follows. Treatment began April 14th:—

Lower Extremities.—By May 31st, their movements were free, tone had been partially regained, and some knee-jerk had appeared. The patient began to walk without support, June 28th; but Faradic contractility was absent from the muscles, and from the anterior crural nerve.

Shoulders and Back.—May 3rd. Slight power existed in the right shoulder only; on the 16th the deltoids and great pectorals were beginning to act, and Faradic contractility showed itself ten days later in these muscles; the latissimus and teres remained powerless. Not till July 18th was there much improvement in the nutrition of the shoulder muscles, and at that time Faradic contractility existed in the pectorals alone. Thence recovery was rapid.

Upper Extremities.—May 16th. Some Faradic contractility was present in the upper extremities. At this time there was general tendency to return of contractility, but with remarkable differences in different regions, varying between 13° of Stöhrer and zero; the zero referred to the calves, which nevertheless were rapidly recovering; illustrating the fact that there is no necessary relation between the return of sensitiveness to voluntary and to electrical stimulations.

June 5th.—There was power of grasp in the right hand; the muscles of both forearms remained perfectly flabby. By the end of the month active Faradic contractility was found in the flexors in each forearm, but not in the extensors, nor in the triceps. Good response followed Faradising the nerves.

The muscles of each thenar eminence alone caused anxiety, especially on the left side; the right thumb was brought in contact with the tips of the fingers with difficulty, the left thumb not at all. Only the second interosseus responded to Faradism of all the muscles of the hand and forearms; and ten days later, notwithstanding the assiduous use of the battery current, neither thumb touched the tips of all the fingers. It was not till early in December that the

extensors on the forearm had recovered. On January 5th, it is reported that the right long extensor of the thumb was restored, and that the patient had dressed herself for the first time.

It will be evident from the foregoing details that although the paralysing influence was general throughout the motor cells in both the cervical and lumbar enlargements of the cord, it had nowhere reached the destructive degree unfortunately not infrequent in certain groups of cells in this disease. Faradic contractility was extinguished for only a limited period; and where it was lost for a time, the battery current was simply powerless, like the Faradic, and in no set of muscles gave any indication of the fatal reaction of degeneration. Nor, again, did the disease remain in any one group of cells, as so frequently happens, to mar the completeness of recovery. I was greatly afraid for a time that the worst consequence—permanent disablement of the delicate operations of the right hand, or at least of the right thumb—might cause us disappointment. Happily this result was averted.

Case II.—Amyotrophic lateral Sclerosis.

T. S., aged 44, watchmaker, admitted July 14th, 1883. All evidence of syphilis and of plumbism is absent. He is of temperate habits, but has been in the practice, for the last twelve years, of smoking half an ounce of strong tobacco per day, and one ounce on Sunday. Mr. Priestley Smith reported his disc to be healthy; but there was a slight central scotoma for colours such as characterises tobacco amaurosis. Perhaps it is worth notice in this connection that Duchenne (Observ. LXX. Anterior Spinal Paralysis of Adult) mentions a patient who had been in the habit of smoking, for twenty years, tobacco containing a large quantity of nicotine, and of drinking a glass of absinthe daily.

The report he gives of the access of his symptoms is very indefinite; he speaks of weakness in his legs of twelve years' duration; but it is evident that the last three years, and especially the last six months, have witnessed marked increase in the muscular feebleness; during the same time, too, the arms have been losing power. His legs felt too heavy; they "gave" under him, and trembled in walking; he has had several tumbles in consequence; his feet have tended to drag, and his knees were wont to shake so much in sitting down, that he was compelled to grasp them; he has felt jumping in his left leg, and has had cramps and stiffness.

I never found any evidence of "contracture;" the spasmodic element was confined to the foregoing description, and to the clonos and tremors to be mentioned. Then his fingers felt numbed, and his tools became loose in his grasp; his hands shook as if from cold. He speaks of troublesome pain shooting from the feet up the legs.

He has found failure in speech for six months—he has broken down in long sentences; and I may at once say that the bulbar symptoms were limited to a decidedly feeble and nasal character of voice, rendering him sometimes unintelligible; and to tendency to regurgitation of food. The sole muscular change, nutritive or functional, consisted in very considerable irritability of the palate muscles. The nutrition and movements of the tongue were perfect.

The patient has lost flesh considerably.

When admitted he was able to walk a mile: the muscular nutrition of the lower extremities was perfect, the muscles contracted firmly, and acted also to Faradism.

The muscles of both forearms were greatly enfeebled, especially of the right; all the delicate movements of the right hand were gone; his power of fixing his arms against his side was much lessened. The right arm had lost half-an-inch in girth; the right palm was hollowed, the thenar and hypothenar eminences were melting away. Very marked fibrillation prevailed in the muscles of the upper extremities and shoulders, and in the pectorals.

As regards the reflexes, the knee-jerk was preternaturally active; tapping the tendo Achillis caused extension of the foot; decided contraction was produced by a stroke upon the flexor tendons of the wrist, and the tendon of the biceps: when tapping the triceps tendon, the contraction extended to the supra and infra spinati muscles.

Clonos was present irregularly; it was sometimes produced with such violence, by resting the toes on the ground, as entirely to prevent locomotion; sometimes it could not be produced, apparently through the restraining action of irritable muscles. The right plantar reflex was more energetic than the left; abdominal reflex was present on the right side alone.

Faradic contractility, though never long absent from the muscles, showed very marked variability.

I need not specify the details of the progress made by the disease; since the patient came under observation, the downward course has been rapid. In two months the right thenar eminence was nearly lost, and the first metacarpal bone lay on a level with the second; the muscles of the forearm had disclosed the interosseal space; the opposite upper extremity was falling into the like condition. Speech was more feeble, but no further development of bulbar symptoms had taken place.

By the end of the sixth month from admission, the right forearm and hand were nearly powerless, atrophy of the muscles of the hand was nearly complete, and of the arm was greatly advanced. Those of the left upper extremity were rapidly wasting. The trunk muscles were in a state of advanced paresis but gave no evidence of having wasted; the patient was utterly unable to raise himself in bed, and turned himself, when lying, only with much difficulty. There was much cramp of the abdominal muscles.

Although it was only by great effort that he could lift his lower extremities to the bed, they retained their nutrition and their contractility. His attitude in walking was very characteristic: the shoulders bent, the head bowed, the arms hanging loosely by the side, and his legs scarcely bent, but swung forward by the movement of the trunk; there was, however, a good deal of variability in the degree of decrepitude; and sometimes clonos on placing his feet on the ground increased his difficulty. The reflexes presented no important change.

HEPATIC ABSCESS OPENING INTO PERITONÆAL CAVITY—SECONDARY ABSCESSES IN BRAIN.

By S. A. K. STRAHAN, M.D.,
Assistant Superintendent, County Asylum, Northampton.

Hepatic abscess is sufficiently rare in those who have never lived out of this country to render its occurrence worthy of record. In the following case the absence of any apparent cause, the increased difficulty in arriving at a definite diagnosis in consequence of the patient's mental state, and the presence of secondary or pyæmic abscesses in the brain, give it an additional interest.

Briefly, the case is as follows:—W. S., a single man, aged 31, an iron moulder, who had never been out of England, was admitted into this asylum in August, 1881, suffering from a second attack of insanity. The

form of alienation from which he suffered was mania, with delusions of a religious nature. He was, on admission, described as "a strongly built, well-nourished man, in good bodily health, save for a slight systolic murmur." For two years after admission he enjoyed—if the insane can be said to enjoy anything—excellent health, and gained about 28 pounds in weight. Mentally he did not improve; his delusions remained fixed; he often threatened to kill the medical officers and others, and was looked upon as dangerous.

On August 8th, 1883—two years after his admission—he first complained of feeling ill and of "pain in the stomach." The temperature ran up to 100°, and the appetite failed (he had been a voracious eater before), but he soon came round, and on September 12th it was recorded, "All pain gone; seems recovered from recent attack; eats and sleeps well." He had lost considerably in flesh during this month's illness. The pain was never severe; he referred it at different times to "his bowels," "side," and "chest," and no definite diagnosis of his case was arrived at.

On September 17th, the pain returned, and the temperature again went up above 100°. He now began to have very profuse night sweats, to be troubled by a short cough, and occasionally to spit, after coughing, little specks of blood. The chest was examined as carefully as his condition permitted without anything definite being made out. On September 20th, the skin and conjunctivæ were jaundiced, and he vomited twice; this called attention to the liver, but examination revealed nothing. From this time the temperature varied irregularly between the normal and 104°; the icteric staining appeared and disappeared, and the stools and urine also frequently changed in colour, the former being often much paler than normal, and the latter at times being high-coloured, and showing, on examination, the presence of bile pigments.

During October the temperature, jaundice, and pain varied as before, but the sweats and emaciation continued. It was noted at this time that the patient's face—generally jaundiced, but never deeply—often changed colour in a remarkable manner. In less than 30 seconds the yellow would fade, giving place to a sickly earthy hue, with bright red patches on the malar prominences. This most effectually changed the aspect of the man, and excited the wonder of the attendants. I may say the conjunctivæ retained their slightly yellow tinge. From the end of October the pain was almost constant, as was also the sweating, the icterus coming and going almost daily. He became irritable and desponding, and would permit no examination. On November 26th, he was held, and an attempt made to define the area of hepatic dulness. This was found to extend from the level of the nipple (he was lying on his back) to within an inch of the crest of the ilium; it reached the middle line at, and for two inches above, the ensiform cartilage, and below, tailed off from that point, in a line running to the centre of the iliac crest.

He now rapidly became more emaciated and weaker; the appetite entirely failed, the pulse—all along frequent—became more frequent and smaller, and he became incoherent six days before death. On December 12th, he had persistent hiccough; on the 13th, he had several epileptiform convulsions; and on the 14th he died, having been unconscious for the last three days. He lay all through his illness on his back, and the legs were fully extended to the last.

An examination of the body was made 27 hours after death, when notes were made, from which I extract the following:—

Cadaver, that of a strongly built man, much emaciated, skin slightly jaundiced, a blood tumour on each heel, and some purpuric spots on toes, fingers, and forearms.

Head.—Arachnoid thickened and opaque in patches over the hemispheres. On removal of the arachnoid, many masses of greenish-yellow pus were found upon the convolutions; these proved to be abscesses of about the size of and in colour very like green peas. On section of the organ, scores of abscesses of similar size and appearance were found in every part, some showing through the superficial grey matter, others in the great white centres, and others again opening—or rather showing, for no pus had escaped—on the ventricular surfaces. The cerebellum was studded in a like manner.

Chest.—Nothing to notice except some hard nodules, apparently inactive tubercles.

Abdomen.—The liver had pushed the diaphragm up to the level of the nipple on the right side. On pressure, pus welled out from beneath the anterior edge of the liver; the intestines were matted together, and were adherent in places to the abdominal wall from peritonitis. In the thick and posterior part of the right lobe of the liver was found a large abscess, which had contained about a pint or more of pus. It had opened into the peritonæal cavity through the under surface of the organ. The liver was considerably enlarged, and lay over the right kidney, which had to be removed along with it on account of the adhesions. On cutting into the liver, many small (secondary) abscesses were found, from the size of a pea to that of a nut. The kidneys appeared healthy to the naked eye; the spleen was black and soft to rottenness.

The following points in this case are worth notice:—This patient had no hæmorrhoids, fistula in ano, dysentery, or other intestinal inflammation, for at least two years previous to the appearance of the hepatic trouble. There was no history of any contusion or other injury, nor were there any hydatids present. What, then, was the exciting cause of this abscess?

Again, the poison carried from the seat of suppuration in the liver by the blood-current first passed through the lungs, to be deposited in the brain. Why were not these centres of infection arrested in the lungs, as is generally the case, there to form the starting points of pulmonary abscesses?

To the ordinary practitioner, another point in this case will appear strange, viz., that the patient, though suffering from severe general peritonitis, lay with the legs extended until the last. This, however, will not astonish those having the care of the insane. I have, within a short experience, seen at least one case where I did not even suspect peritonitis; where the patient, until the last day of life, rolled about, and frequently got out of bed, and where, on *post-mortem* examination, the intestines were found one mass of adhesions from recent inflammation. And I have recorded another case, where the patient, though not oblivious to pain, went through peritonitis after herniotomy, without any increase in the temperature or quickening of the heart's action.

Slow Increase of Population in France.—From a return published in the *Journal Officiel* it appears that there were 280,460 marriages in 1882, in place of 282,079 in 1881, and 935,566 births in 1882, in place of 937,057 in 1881; and 838,539 deaths in 1882, in place of 828,818 in 1880. It is a fact, therefore, that the unfavourable condition of the country, as regards increase of population, continues, or rather is aggravated. As far as such increase is dependent upon the augmentation of births as compared to deaths, the rate of increase is only 0·26 per cent. per annum—the population only doubling itself in 267 years. The doubling, however, takes place much more rapidly than this, viz., in 165 years, owing to the great and increasing number of foreign immigrants.

REPORTS OF

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

GENERAL HOSPITAL FOR SICK CHILDREN, MANCHESTER.

CONGENITAL HEART-DISEASE—ATRESIA OF THE PULMONARY ARTERY—STENOSIS OF THE TRICUSPID ORIFICE — PATENT FORAMEN OVALE AND DUCTUS ARTERIOSUS.

By HENRY ASHBY, M.D., M.R.C.P.,
Physician to the Hospital.

FLORENCE S., aged two and a half weeks, was admitted to the Children's dispensary July 5th, 1883. She was a first child, and at birth it was noted that she was "blue as a winberry." The mother was subject to "fits," and had had fits shortly before the child was born. She had never miscarried. The infant when first seen was cyanosed, the tongue, lips, mucous membrane of the vagina being of a lurid purple colour; the heart sounds were normal, there was some loss of resonance at the bases of the lungs posteriorly, but the air seemed to enter everywhere.

October 15th.—Child still blue, but less so than when last seen; nutrition good, has grown fairly well, no cardiac bruit detected.

October 25th.—Was put to bed apparently well; next morning it was noticed to be very blue, there was some bleeding from the nose and mouth, and the child (now four months old) died in a few hours, having been previously convulsed.

At the *post mortem* the only organs examined were the heart and lungs. The lungs were crepitant throughout, and on section displayed various masses, from the size of a pea to a marble, of pulmonary apoplexy. On viewing the anterior aspect of the heart, it was noted that at least three-fourths of the ventricular surface was occupied by the left, the right ventricle occupying the remaining fourth and feeling quite solid. *Right auricle.*—On opening the cavities, the right auricle was found to be much dilated, its walls thickened, the coronary sinus dilated, the foramen ovale open, the tricuspid orifice contracted so as only to admit a goose quill. On cutting into the *right ventricle*, the walls were found to be thick, out of all proportion to the size of the cavity, the former being over half an inch in thickness, while the latter was only large enough to contain a small marble, the two surfaces being in contact. The tricuspid valves were diminutive, their edges partly adherent, so that the orifice would only admit a probe the size of a crow quill. The pulmonary artery was small, the semi-lunar valves distinct, but adherent to one another, so that the pulmonary orifice was completely obliterated. There was no communication between the ventricles through the septum. The ductus arteriosus was patent, and about the size of a crow quill. *Left auricle.*—Cavity of moderate size, wall thin, mitral orifice readily admitting the forefinger. *Left ventricle.*—Cavity capacious, large enough to contain a walnut, wall one quarter of an inch thick, mitral and aortic valves healthy.

Remarks.—The direction taken by the blood through the heart must have been in the following way:—The blood delivered into the right auricle by the superior and inferior venæ cavæ and coronary sinus, must have over-distended the auricle, gradually passing through a somewhat small foramen ovale into the left auricle to mix with the blood, brought there by the pulmonary veins. The atresia of the pulmonary artery and stenosis of the tricuspid preventing any exit in that direction. The whole of the blood entering the heart would pass through the mitral orifice into the left ventricle, thence through the aorta, a portion entering the innominate, left carotid, and sub-clavian; a second portion passing through the ductus arteriosus into the pulmonary artery, and through the lungs; the third portion being delivered to the lower part of the body by means of the descending aorta. With this arrangement, it is evident that marked cyanosis must exist.

In this case it is clear that an endocarditis affecting the pulmonary and tricuspid valves occurred at an early period of fœtal life, resulting in the complete closure of the former orifice and the partial closure of the latter, traces of the process being left in the thickened and opaque endocardium near the orifices referred to. The right ventricle no longer giving passage to the blood became contracted, and the interventricular septum closed; after birth the foramen ovale remained patent, as it was the only outlet the right auricle possessed, and the ductus arteriosus also remained open, as it was utilised for the passage of blood from the aorta to the lungs.

Medical Times and Gazette.

SATURDAY, MARCH 15, 1884.

AMONG the many and various subjects that are brought before Parliament at question time, that of the evils caused by over-work in Board schools continues to hold a prominent place. On Friday last the Vice-President of the Council was asked, in effect, what he thought of the memorial signed by more than fifty of the medical men of Bradford and addressed to the School Board, praying that they would direct that home lessons should not be enforced upon children under ten years of age; and whether he proposed to take any steps to limit pressure in that direction upon children of tender age. Mr. Mundella said, in reply, that he had considered the memorial referred to, and found that some of the statements made by those who presented it, as to the prevalence of brain disease among children, were not confirmed by the Registrar-General's returns. The Educational Department had taken special precautions to prevent children from being over-worked in their schools by directing that exceptionally dull children, or weakly or delicate children, or those who had suffered from prolonged illness, should be withheld from examination; by ordering managers of schools to see that such children be not unduly pressed during the year prior to examination; and by enabling children who have failed in two subjects, or twice in one subject, to be re-examined in the same standard. The Department would direct her Majesty's inspectors to see that these rules are carried into effect; but he added, seeing that there are nearly 5,000,000 children on the rolls of public elementary schools in Great Britain, "no regulations that the Department can lay down will be effectual unless parents, teachers, and managers will co-operate with us to protect the children."

The same subject was brought forward on Tuesday last in the House of Lords by Lord De La Warr, who, in a long speech, dwelt on the frequency of educational over-pressure, and referred especially to the Bradford memorial, and to the case of the child whose death from inflammation of the brain is said to have been hastened by over-work in a school at Cheltenham. With regard to this case, it appears that the child did not belong to a School-Board school; and Lord Carlingford was able to state that the school she did go to was an exceptionally good one, presided over by an exceptionally experienced mistress. The evidence given at the inquest held on the child showed she suffered from tubercular meningitis and from disease of the lungs, and the jury returned a verdict to that effect, adding as a rider that no blame attached to the teachers or the school authorities. Respecting the Bradford document, Lord Carlingford's statement was very much the same as that made by Mr. Mundella; and he further adduced some statistics to show that people need not fear that the Education Department had any wish to stimulate children to work at special subjects at the sacrifice of essential education. Special subjects cannot be taken in any school which has not passed 70 per cent. of the children attending it through the ordinary standard of education. That regulation, of course, reduces the number of children who can take up special subjects; and in a report recently made by one of the inspectors he stated that out of 17,000 who had been examined in Manchester there were only four per cent. who had taken up special subjects. The New Code certainly does not seem to err in the direction of pressing the study of such subjects; for, to take only one of these subjects—animal physiology, in the four months before the New Code came into operation in England and Wales, 22,000 children took up that subject; but during the four months that had elapsed since the New Code came into operation, it had been taken up by only 4,800 children.

On Wednesday Mr. Reid, having obtained the leave of the House, brought in a Bill to prohibit vivisection, and it was read a first time.

At the Ordinary Meeting of the Royal Medical and Chirurgical Society on Tuesday last, Dr. George Johnson, F.R.S., the newly elected President, in taking his seat for the first time, thanked the Fellows for the honour done him, and expressed the pleasure which his election had afforded him. His term of office was inaugurated by two papers, both on somewhat unusual subjects, but of great and varied interest. The first one was a further communication on Artificial Respiration in Stillborn Children. Dr. Champneys pointed out some of the mechanical difficulties which prevent the successful accomplishment of artificial respiration as generally practised. An interesting discussion ensued, from which we may anticipate practical advantages. The second paper was by Mr. J. B. Sutton, who advocates the systematic examination of the bodies of all stillborn children. He believes that many useful lessons will be learnt, not alone concerning malformations and deviations from the standards which are considered normal, but also concerning intra-uterine disease and its effects on development and growth generally. Mr. Sutton showed many interesting specimens, which he had found in the bodies of fœtuses, in support of his contention.

The Medical Society of London, the oldest Medical Society in this country, if not in the world, celebrated the completion of its 111th year of existence, by its anniversary dinner on Saturday evening. The dinner, which took place in the Venetian Hall of the Holborn Restaurant, was presided over by the out-going president, Sir Joseph Fayrer, and was distinguished by the presence of the presidents of several other learned societies, including Professor Huxley, representing the Royal Society, Mr. Hulke, who has just vacated the chair of the Geological Society, and Dr. George Johnson, who has just stepped into that of the Royal Medical and Chirurgical Society. There were many speeches, the most noteworthy being of course, that of Professor Huxley. The "uncrowned king of science," as Sir Joseph Fayrer aptly called him, lauded medicine for what it has done in the past for science, and vituperated the Government for what it is going to do for medicine. Thirty years ago, said Professor Huxley, a medical education was the only entrance to the study of chemistry and biology. The Medical Bill, he said later on, was pedantic in its conception, and would be disastrous in its results, a prophecy which was not loudly applauded by his hearers. Sir Joseph Fayrer made many graceful speechlets, and gave the Fellows the very sound, but rather uncourtierlike advice, not to rely for their success on such incidents as Prince's visits, but on their own exertions; to which we may add the advice not to depend too much on their Presidents. The Society cannot expect to have a succession of Sir Joseph Fayrers in its chair.

Nature gives a list of officials at the meeting of the British Association, which will be opened at Montreal, on August 27th, under the presidency of Lord Rayleigh. The list of vice-presidents includes the names of Sir Lyon Playfair, Professor Frankland, the Hon. Dr. Chauveau, and Dr. W. H. Hingston. The biological section, which is the one in which the medical profession takes most interest, will be presided over by Professor Moseley, while Dr. W. B. Carpenter holds office as one of the vice-presidents, and Dr. W. Osler, a Montreal physician well known both in London and Edinburgh, is one of the secretaries. Beyond these names, there are but few members of the medical profession on the list. Now that science is so specialised, a doctor who can shine in other branches as well as his own is a phenomenal being.

In a lecture at the Westminster Hospital, a few days ago, on Asiatic cholera, Mr. Macnamara took the opportunity to make some observations on the recent outbreak of cholera in Egypt. As regards the cause of it, he lays stress upon the interference with the working of the sanitary service in Egypt during the previous autumn by the war, and also to the influx of

native Indian troops on that occasion. That the cholera did not spread to Europe last year is, in his opinion, to be attributed to the rigid quarantine measures adopted by most of the countries, rather than to the sanitary precautions taken by our own Government. He considers that at all times it is a difficult matter to trace the origin of an outbreak of cholera; and that it was especially difficult in this instance, but Sir W. G. Hunter went to Egypt with preconceived opinions, and it was not surprising, therefore, that he failed to trace the mode of importation. In conclusion, Mr. Macnamara expressed himself a strong believer in the communicability of cholera, both from his own personal experience of the disease, and from a careful study of its history. He holds that no amount of insanitary conditions, or any other circumstance, can produce an attack of Asiatic cholera, except the infecting matter passed by a patient suffering from the disease is swallowed, and that the infecting matter must pass into water or food containing certain unknown elements to render it an active poison when swallowed.

The Edinburgh University students held a crowded and enthusiastic meeting, on Saturday last, to discuss a proposal to establish a students' union. The estimated cost of the building is no less than 12,000*l.*, but this did not seem to dismay any of the speakers, for no one even hinted at the possibility of there being any difficulty in raising this sum. We hope that the result will prove that their calculations as to the length of their own and their friends purses have been well founded. But in undertakings of this sort we fancy that a gradual commencement is the more prudent course, and if we are not mistaken, the Cambridge University Union commenced its career in a very small way as compared with the building it now occupies.

On an afternoon last week, Mr. John Furley, of the Ambulance Association of St. John of Jerusalem, gave a short practical demonstration to the porters of St. Mary's Hospital, on the best method of lifting and carrying sick and injured patients. It is well that the hospital porter should now and then be shown that there are improved methods of moving patients, for one may say of him with Horatio, "Custom hath made it in him a property of easiness." The servants and staff of the hospital were greatly interested in the demonstration, and worked with a will under Mr. Furley's instructions. Probably other hospitals would be glad to receive such a visit from one so well skilled in ambulance work.

In all the large centres of population, in the United Kingdom, except Birkenhead, Glasgow, and Paisley, the death-rate went up with a jump last week. The rate of the 28 English towns, which was 20·3 in the previous week, mounted last week to 22·5, and that of London from 19·3 to 21·3, or higher in both cases than it has been since the first week of the year. The zymotic death-rate, both in the metropolis and the provincial towns, stood higher than it has done for weeks. In London, the deaths from zymotic diseases numbered 215, against 179 in the previous week, and were only seven below the decennial average. This increase is mostly accounted for by the greater fatality of whooping-cough and measles. There was also an increase of 50 in the number of deaths from respiratory disease, though they were still 107 below the average. Small-pox seems slightly on the increase in London, though only one death was recorded last week.

The Medical and Dental Registers for the present year have just been published. They have both been subjected to a very careful revision, and contain in the introductory matter all the Medical and Dental Acts, and full and exhaustive data as to the statistics connected with the present and previous issues of the Registers. From the Medical Register it appears that 1,304 new names were registered in 1883, as compared with 1,171 in 1882, 1,053 in 1881, and 1,123 in 1880. The names removed from the Register in the course of last year numbered 710, a smaller return than in any year since 1876; so that it is to be hoped that the present Registrar's persevering efforts to keep his records correct are bearing fruit. The new Dentists' Register contains 5,296 names, of whom 801 possess licences in dental surgery, 22 surgical qualifications without dental licences, and five foreign dental diplomas. The last-named class has apparently not increased since the Dentists' Register was first instituted.

The curiosity as to the details of criminal executions, which has of late been unwisely fostered by the publication of the proceedings and alleged irregularities of the common hangman, will probably be followed in due course by a protest from some well-meaning, but ill-informed, association of philanthropic ladies and gentlemen, condemning the use of "long drop" or "short drop," as the case may be, with a zeal worthy of all other phases of anti-agitation, and resting on the usual basis of incorrect statement of facts and unreasonable deductions from them. Already we have heard the indignant voice of the British householder condemning the want of skill which, while completely severing the bony continuity of the spinal column, has failed to stop the action of the heart for several minutes! The suffering which such a state of things must entail, whilst too terrible for words, would naturally thrill the heart of the unphysiological reader with "holy anger and pious grief" indeed. To ask such a one to separate in his own mind the notion of sensitive life from that of the pulsation of the heart would, perhaps, be too much. Certain phenomena, however, which have lately been observed at a triple criminal execution at Prague may, perhaps, be with advantage brought before him. The three criminals were hanged together, and no doubt could exist as to their almost instantaneous death. In all three cases the hearts continued to pulsate for nearly a quarter of an hour afterwards. Looking back to the history of the subject, many cases may be found recorded where the heart's action has continued for a long time after complete decapitation. It is certainly to be desired that further scientific observations should be made upon this point, if only as a means of checking the sensational effusions of professional horror-mongers.

In our last week's notes on the Magazines, we ought to have mentioned that the *Leisure Hour* for this month has two subjects of more or less medical interest, the one a very sensible article on "Hospital Nurses," by Miss E. Harkness; the other a string of anecdotes of "Doctors out of Practice," by Mr. Cordy Jeaffreson. Miss Harkness writes with a good sense and good taste, that unfortunately have not always distinguished writings on hospital nurses from the nurse's stand-point; she admits that there were many lessons which the lady nurse could have learnt from the style of nurses previously employed—lessons of obedience, truthfulness, punctuality, loyalty, and cheerfulness. She thinks that a hospital matron ought to have considerable knowledge of all classes of society, and should, if possible, be good-looking, and a woman who knows how to dress. Another sensible remark is that people should be encouraged to send nurses tickets for places of amusements. Mr. Jeafferson's anecdotes of "Doctors as Politicians" are mostly well known. He relates some amusing instances of the active part which certain highly placed members of the profession took in politics in the eighteenth century. Some at the present day express themselves as anxious to restore that activity, but for our part we must confess that we have little liking for medical politicians. Neither Virchow nor Paul Bert has gained in forsaking science for the Senate.

Diphtheria is alarmingly on the increase in Paris; the number of deaths have shown a steady rise during the last five weeks, the figures being 43, 60, 52, 70, and last week 75. The average deaths from diphtheria in Paris at this time of the year always amount to from 40 to 45 weekly, but it is long since such a figure as 75 has been reached. The districts in which it is most prevalent, are those of La Roquette, Sainte Marguerite, and Les Quinze Vingts, all in the close neighbourhood of the Hôpital Trousseau.

M. Floraud supplies to the *Revue Mensuelle des Maladies de l'Enfance* some interesting statistics relating to the cases of diphtheria, admitted to the Hôpital Trousseau, in Paris, during 1883. There were 606 cases of diphtheria admitted, of which 165 were pharyngeal, while 441 affected the larynx, or air-passages. Amongst the 165 cases of pharyngeal diphtheria there were 65 deaths, making a mortality of nearly 40 per cent. The 65 deaths included ten from paralysis, the rest dying from the toxic effects of the disease, or of measles, or scarlet fever. Of the 441 diphtheritic croups, 359 were operated upon with 244 deaths, a mortality of 68 per cent. The 359 cases operated upon included 40 cases of croup complicating measles, and 30 who were under two years of age; and among those who recovered after tracheotomy, there was an infant of thirteen months, three under twenty months, and two which were complicated with measles. The cases which were not operated upon were for the most part those cases in which there was wide-spread diphtheria of both pharynx and larynx, and which were moribund when admitted. These results are said to be the most satisfactory which have been obtained for many years at the Hôpital Trousseau. It is interesting to note that several cases of paralysis occurred after *laryngeal* diphtheria, thus pointing strongly to the identity of pharyngeal diphtheria and "membranous croup."

The *Archives of Pediatrics*, the first two numbers of which have lately reached us, is, we had better explain, an American monthly periodical devoted to the diseases of children. The communications and lectures are so far decidedly good, and augur well for the future success of the journal, in spite of its somewhat uncouth title.

An American contemporary has been giving its views on English Medical Journals. It is kind enough to say that in the purely journalistic and technical part of the work of editing and publishing medical periodicals, England is ahead of any other country, though America is now pressing closely upon it. "A characteristic of English journalistic work is the literary skill displayed; the editorial writing is generally careful and often forcible, while the editors are remarkably apt in turning every-day events into 'material,' and in throwing a medical — not to say 'bony' — light upon them. We are obliged to say, that undoubtedly another not so admirable characteristic of English editorial work, is the union of a certain heaviness of style with triviality of subject, the result being a kind of medical *bathos*—which is the hypnotic quality in leading articles."

The *Lancet*, in our contemporary's opinion, still retains its pre-eminence as the leading exponent of English medical journalism, and it has undoubtedly helped to give dignity and force to medical opinion. "We venture the criticism, however, that it goes too far at times in peddling out gratuitous sanitary instructions to the laity as regards every conceivable social custom or individual habit. The *Lancet* exhibits an extraordinary facility in discovering the medical significance of contemporaneous incidents, and can write profoundly and medically upon all things from the war in Egypt to the *accouchement* of a duchess." The *British Medical Journal* is declared by our contemporary to be truly a wonderful periodical, though its size is a little appalling. It is doing an effective work in consolidating the medical profession and increasing its political influence. The *Medical Press and Circular* "is not inferior to the other weeklies in the editorial ability which it displays." No one can take umbrage at such charitable criticism.

In the March number of the *Practitioner*, Dr. Shelly advocates the use of peroxide of hydrogen as a local antiseptic and astringent. In all forms of ulcer it exerts a beneficial action, especially on syphilitic cases. It is also useful in purulent ophthalmia, otorrhœa, gonorrhœa, leucorrhœa, and in stomatitis and ozæna. Dr. Shelly without wishing to praise it unduly, says that it possesses "powerful antiseptic properties, and moreover is colourless, odourless, cleansing, and stimulating, does not stain or corrode, destroys pus, causes no pain in its application, and is not poisonous."

The annual report of Mr. Thomas Partridge, the Medical Officer of Health for the Rural Sanitary District of Stroud, is before us. There is nothing unusual in the statistics, and nothing exceptional in the epidemic incidence of disease to be found in the summary of the year's work. If the baldness of events were a sign of excellent administration, we would say, Happy the officer for Stroud!! Fortunate the district to have no history! but, reading between the lines, we make the discovery that if to meet and talk, and talk but never act; if to leave all necessary improvements to the uncertain empiricism of private benevolence, to build refuges for the sick out of the personal property of charitable individuals; if in short to ignore every representation made to it by its officer, and to neglect the most important duties laid upon it by the law, constitutes a Sanitary Authority, then Stroud possesses one; but if, as some would maintain, these qualities of somnolence, torpor and inaction rather belong to ancient guilds than to modern institutions, the sooner a change is made in the administration of sanitary matters, at Stroud, the better. That these strong remarks are not uncalled for, may be proved by the following extract: "*Drainage.*—No proper system is carried out anywhere in the district; Stonehouse has talked about it for years, and Painswick is in a similar position. Rodborough, is in an equally bad state. At Minchinhampton, by the generosity of Mr. Ricardo, the old sewage is being improved and extended to the bottom of the town." In another place we read that a certain Miss Davies has built a cottage hospital, which seems to be a useful institution. Comparing little things with great, what utter contempt for the Corporation of the City of London we should feel if, after waiting years and years for a vital sanitary improvement, it availed itself of the purse of a private citizen to do work cast upon it by Acts of Parliament. How would it be if the Asylum's Board advertised for philanthropists to erect, at their own expense, infectious hospitals? The whole country is now so inter-dependent, that we can no longer pass over the inaction of any small or obscure sanitary authority without caustic comment—if disease does not yet speed with the electric fluid, it is carried along the rail; a few insanitary farms may throw a whole city into mourning, and there is no part of the island, however remote, the sanitary condition of which may be ignored. Before leaving the subject of Mr. Partridge's report, we should like to add, that it seems bad policy, and serves no useful purpose, to permit inspectors of nuisances to make annual reports in the form and style of the two before us. If discipline is to be maintained and the health officer to hold a proper position, all communications of the kind should be made to him, and not direct to the Sanitary Authority.

Many complaints having reached the Local Government Board as to the water supply of the litte watering-place, called Burnham, on the shore of the Bristol Channel, Dr. Blaxall was despatched to make an enquiry into the subject. Briefly considered, his report showed that the water supply of this town was entirely derived from wells sunk in a soil exposed to pollution by soakage from surface filth, by decaying organic matter from the overcrowded churchyard, in which the digging of a new grave meant the turning up of human remains, and by casual leakage from the sewers and drains. Out of twenty-three samples of well water, from this locality, examined during recent years, not one obtained unqualified approval, while many were totally condemned, and one was described as only fit for irrigation purposes; speaking of this latter water, the Medical Officer of Health explained that when kept boiling it gave off steam pungent with ammonia. Of the two or three schemes laid before Dr. Blaxall to remedy this grave defect, the one which appeared to commend itself most to his attention was that for entering into arrangements with the Bridgwater authority to extend their mains to Burnham, a distance of some seven or eight miles only, with a gentle fall all the way. The inhabitants of Burnham are not alone concerned in the sanitary condition of their town, since the public who frequent the watering-place in summer-time have a direct interest in it, and should assuredly be protected, as far as practicable, from the risk of contracting preventable disease through drinking water dangerously contaminated.

In the notice of "Men of the Times," which appeared in these pages a few weeks ago, all mention of the brief epitome of Mr. G. R. Jesse's achievements, which adorns that work, was advisedly omitted, as Mr. Jesse has quite sufficient means of publicity without any help from us. But as the *Saturday Review* has thought Mr. Jesse worthy of its pillory, we will not further deprive our readers of the entertainment which they will doubtless derive from perusing the picture of Mr. Jesse as he appears to himself. "In February, 1877," we read, "he founded 'The Society for the Abolition of Vivisection,' and he was greatly instrumental in obtaining the appointment of a Royal Commission to enquire into the practice of subjecting live animals to experiments for scientific purposes, and gave evidence before it for three days." In consequence of the controversies between Mr. Jesse and Dr. Ferrier, Dr. J. Crichton Browne, Dr. T. Lauder Brunton, Mr. T. Spencer Wells, Professor Owen, Mr. Darwin, and other distinguished scientific men and members of the medical profession, Government now reverses the decisions of the Presidents of the Colleges of Physicians and Surgeons, and refuses point blank to grant licences to some physiologists of wide-spread repute. The licences were applied for for carrying on investigations which those gentlemen declared to be of the highest value to medical science. The editor of the leading medical journal of England, the *Lancet*, stated in a leading article on November 19th, 1881, that "the part of physiological research which depends on vivisection is being gradually stamped out." On March 9th, 1882, by invitation of the President, Mr. Jesse read a paper in Birmingham, at the Birmingham and Midland Counties Branch of the British Medical Association, controverting the assumption that "scientific surgery is founded upon vivisection." The injurious and sustained assaults made by Mr. Jesse on the physiological citadel forced the Colleges of Physicians and Surgeons to found, on March 28th, 1882, an association for the "Protection of the Right of Vivisection," entitled the "Association for the Advancement of

Medicine by Research." Owing to the persevering exertions of the Society, created by Mr. Jesse, the agitation against the practice of painfully experimenting upon animals for scientific purposes has now, Professor Virchow admits, "in all countries attained a dangerous degree of vigour," and spread widely through England and Europe. Mr. Jesse is honorary secretary to this Society, and has written many pamphlets on the subject of vivisection.

The antiseptic fever—if we may coin a term which would, in some quarters, be regarded as almost indictable — appears to be in temporary recrudescence amongst our Transatlantic brethren, to judge from the large space which the subject occupies in recent American medical literature. In a former number we briefly abstracted a paper by Dr. Thomas, on the prevention and treatment of puerperal septicæmia, in which an elaborate antiseptic programme is described and recommended. Other writers have been contributing their views in the same vein, and the *New York Medical Journal*, for Jan. 19th, contains an interesting account of the antiseptic substances and methods which are employed in the New York Hospital. This is usefully supplemented by a paper descriptive of the various dressings which are, and have been from time to time, made use of in various European clinics, from the pen of Dr. Robert F. Weir—who, by the way, refers to "the too imperfectly honoured Sir Joseph Lister," as one whose successful labours in saving life appear to those on that side of the Atlantic to be worthy of higher recognition than the baronetcy which has just been bestowed upon him.

Dr. Weir pertinently remarks that the general practitioner can hardly be expected to have at his command all the materials which are at hand in a large and well-managed hospital; he may, however, as is pointed out, "have sundry powders of corrosive sublimate, of eight grains each, in his possession, and when called to a case of injury can rapidly add a pint of warm water to one of these powders, bathe the wound freely with the solution, dip into it some cheesecloth—or, what is even better, some absorbent cottonwool—then squeeze this out as dry as possible, or partially dry it by heat, and apply it to the wound. Drainage can be accomplished by perforated rubber tubing; and such a dressing, secured with a bandage dipped in the same solution, will answer for a first application, and permit you subsequently to prepare a more elaborate antiseptic appliance if you wish."

The question is still sometimes asked—does all this carefulness of detail "pay"? If statistics count for anything, the answer is not far to seek. To ask whether the success which is paraded on all hands is due to the careful employment of antiseptic precautions "or to cleanliness," is rather to beg the question. Antiseptic treatment, which is not surgically "clean" in all its details will not secure asepsis; and asepsis is recognised as the *beau-idéal* of cleanliness. The surgeon who adopts antiseptic treatment with the view of saving himself or others the trouble of maintaining rigid cleanliness must fail of his ideal if he stop short of either, and will attain both ends if he succeed in securing one. While he who has given a prolonged and honest trial to antiseptic treatment—even if he ultimately discard it in favour of less elaborate but not less careful details—cannot fail to have learnt and practised many points of special management and treatment which will assuredly stand him in good stead under any circumstances, and which will go far to explain his successful handling of methods which may seem, to the superficial observer, to bear no kinship to rigid "Listerism." The conflict, indeed, is one of words and phrases rather than of principles; and it is interesting to observe men pressing steadily towards the same goal, animated by the same motives, moving abreast upon paths which are not merely parallel but so practically one and the same that the travellers are separated only by that invisible partition which represents their own individuality or the bias of their critics.

Like all young subjects, however, antisepticism can evolve its own Nemesis from the rampant impracticabilities of extravagant enthusiasm, and can write its own sermon on the text "Is life worth living?" One of the most remarkable illustrations of the "Abuse of the imagination in Science" is furnished by a correspondent, in a recent number of the *New York Medical Record*, who, "in view of the great danger to the puerperal woman through the genital canal, and the *very great* difficulty experienced in employing proper prophylactic measures, as so clearly elucidated in the papers recently read before the different Medical Societies in New York," writes to suggest "that the Academy appoint a committee to investigate the advisability of instructing the 'gentler sex' (and, if thought necessary, make it compulsory) to wear an antiseptic pad over the valva from the inception of the catamenia until the menopause, to be non-removable without strict antiseptic precautions or under the carbolic spray."

Readers would probably regard this effusion as a joke of dubious quality, were it not that the same gentleman adds a postscript to the effect that his suggestion does not arise by any means from a theoretical standpoint, since he has had "a patient under such treatment, and as she escaped" puerperal fever, he thinks it a move in the right direction. It is obvious that the principle is one capable of much wider application, and that, if worthy of being adopted at all, it should be carried out completely. Immediate death and cremation, or solitary confinement for life—according to the decision of a Conjoint Board—should be the only alternative to taking our meals under the spray, constantly breathing a thymolised atmosphere, and slaking our thirst only with aseptic beverages.

Dr. B. Kraus, the editor of the *Allgemeine Wiener Medicinische Zeitung*, announces in the number for the 12th February that a microscopist is wanted in Paris, who is especially familiar with the investigations of bacilli. The post is to be a permanent one in a micro-

scopical institute of Paris, and a honorarium of 100 francs will be paid every month, which will soon be raised. This opportunity is recommended to any candidate or practitioner who wishes to pursue his studies in Paris, as he will at once be introduced into the best Medical Society of the French capital.

The occurrence of a distinct form of micro-organism in the sputa of persons affected with croupous pneumonia, already demonstrated by Friedländer and others, has been rendered still more certain by experiments made in Holland by Drs. Poel and Nolen. The former, having exceptionable opportunities of examining the bodies of animals dead of pneumonia, found these micrococci in abundance, the capsule which has been described as their distinguishing characteristic being very plainly visible. Similar organisms were at the same time obtained from cases of pneumonia in the human subject, and specimens of each were cultivated in special media. The resulting micrococci were found to be microscopically identical. Inoculation experiments were then made with each cultivation separately, but the results obtained were again exactly similar. The identity of the virus in the pneumonia of men and animals would seem, by these experiments, to be clearly made out.

Some interesting particulars of the dispensary department of King's College Hospital were presented at the Annual Court of Governors recently held. Within the last twenty years the amount paid for drugs, excluding carbolic acid, has decreased rather than increased, in spite of the addition of new wards to the hospital. The average drug expenditure of the four years 1864–1867 was just over 628*l.*, whereas the drug-bill for 1883 (excluding carbolic acid) amounted to only 598*l.* Carbolic acid first appears in the dispensary books in 1866, in which year the cost was 5*l.* 8*s.*, the price paid being half-a-crown a gallon. The acid now in use is more than ten times as dear, and last year the hospital paid 126*l.* for this drug alone. The amount used steadily increased from the year of Professor Lister's appointment, up till 1881, since which date there has been a slight falling off. Within the same period, as might be expected, the bill for methylated spirit has shown a steady rise. In 1878, only 96 gallons were used, costing 21*l.*; in 1883, the amount used had risen to 480 gallons, costing 70*l.* Thus when the extra expense entailed by the extended use of antiseptic treatment is subtracted, it will be seen how much less is spent on drug treatment at King's College Hospital nowadays than twenty years ago. We should like to have had an opportunity of comparing these statistics with a comparative statement of the amount of alcohol consumed in the surgical wards before and since the adoption of antisepticism. The laudable pus that the old surgeons were so fond of, must have consumed a good deal of brandy that is not needed nowadays, not to mention the extra stimulation required by the erysipelas and pyæmia that were once not unknown at King's. We imagine that carbolic acid, expensive as it is, saves ten times its cost in the long run. In the same return from which we have gleaned the above figures, it is stated that the legacies to the hospital have greatly fallen off of late. For many years the amount received from this source averaged 6,000*l.* a-year, but the average of the last three years was only 1,300*l.* The falling off is probably only accidental.

It is high time for the profession to throw over once for all the foolish pedantry of writing the directions in a prescription in a language which ninety-nine out of a hundred prescribers are utterly ignorant of, even in its canine variety. The most obstinate latinists at the College of Physicians probably agreed with us when they came across the following prescription by one of their members in last week's *Lancet*:—

> "℞ Infusi foliorum recentium saxifragæ, ʒiii. [Faciat, ex aquâ calidâ, xcviii.° Fahr., per horas sex; foliorum i., aquæ x.] Glycerini, ʒi. Misce. Fiat injectionem, ut bis die utendum."

There is considerable *naïveté* about that prescription.

The rumour to which we alluded last week, that there was some probability that an Oxford Medical Graduates' Club would shortly be formed, has speedily been verified. At a meeting, held on Wednesday last, of Oxford graduates practising medicine or surgery it was unanimously agreed that such a club should be formed, and April 4th was fixed for a general meeting to be followed by a dinner. The Secretaries are Dr. Samuel West, 15, Wimpole Street, and Mr. John H. Morgan, 68, Grosvenor Street, a sufficient guarantee that the scheme will be made a thorough success.

Dr. Clifford Allbutt's third Gulstonian Lecture, on the Neuroses of the Viscera, will be delivered this (Friday) afternoon at the Royal College of Physicians. We publish in the present number abstracts of the two previous lectures, though it must be admitted that the second lecture, with its long and valuable series of skeleton cases, does not well bear abstracting, but should be carefully studied when it appears in its complete form. The lectures ought to have a marked effect on the practice of the profession.

THE MEDICAL ACT AMENDMENT BILL.

The Government Bill for the Consolidation and Amendment of the Law relating to the Medical Profession has been promptly introduced into the House of Lords, and was read a second time, as we last week stated, on Thursday the 6th instant. The measure is, with one rather important and two slight exceptions, exactly the Bill of 1883, as, after it had been considered and amended in the House of Lords, it was introduced in the Lower House, only to be abandoned, without having got a step farther, by its authors at the close of the Session. The slight changes, by which we do not mean the improvements in drafting made in the measure, are certainly acceptable amendments though small ones. In the clauses defining the conditions upon which colonial and foreign practitioners will be entitled to registration in the "Medical Register" without examination

in the United Kingdom, words have been added requiring that each such applicant for registration, besides proving that he holds some recognised colonial or foreign medical diploma and is of good character, must further show "that he is by law entitled to practise medicine, surgery, and midwifery" in the British possession, or foreign country, from which he obtained his diploma. The significance and possible importance of the added phrase will be recognised, when it is recollected that medical degrees and diplomas do not in all countries carry a licence to practise—a State examination also having to be passed before that privilege can be obtained. The only other small alteration that we have noticed occurs in Part IV., Clause 29, which provides for the correction of the Medical Register. By the Act of 1858, and by the Bill of last year, the Registrar was authorised to erase from the Register the name of any practitioner who left unanswered, for six months, letters of enquiry from the Registrar; but the Bill of the present year provides further that, when no reply has been received from a practitioner within the stipulated time, the Registrar "shall place the name of such person on a separate list for one year, after which period that person shall" be deemed to have ceased to practise, and his name may be erased from the Register without his consent having been obtained. An additional protection is thus afforded practitioners against the consequences of mistakes of Post-office officials, or of their own neglect or carelessness.

The important alteration in the Bill, to which we have alluded, concerns the constitution of the Medical Board for Scotland. The universities in that division of the kingdom were by the Bill of 1883 granted eight representatives on the Board, and the medical corporations only three. By the present Bill no change is made as regards the representation of the universities, but two more representatives are given to the corporations. Instead of giving one representative to each of the three corporations, two are to be chosen by the Royal College of Physicians of Edinburgh; one by the Royal College of Surgeons of Edinburgh, and one by the Faculty of Physicians and Surgeons of Glasgow, each voting as a separate elective body; and one by the College and by the Faculty voting collectively. The device of dividing the fifth representation between the College and the Faculty is a rather curious one; but the granting of two more representatives to the corporations, while still leaving to the universities a decided preponderance of representation on the Board is wise and polite, and may perhaps disarm the opposition of the corporations. No similar sop is given to the Irish corporations; and it may be expected that those bodies will continue to oppose the measure to the utmost of their powers. Indeed, the College of Surgeons in Ireland has already commenced active hostilities; and a deputation from the Council of that body, a short while ago, interviewed the Lord Lieutenant with the object of entreating him to use his influence to obtain the reconsideration of the establishment of the proposed Medical Boards, which the College regard as unnecessary, injudicious, and detrimental to the public. It hardly need be added that the Lord Lieutenant did not sympathise with the College in their views and alarms; but he kindly advised them to place themselves in direct communication with Lord Carlingford. We do not think the Bill a perfect one, or that *all* its provisions are either necessary for, or best calculated to promote, the efficiency of the profession, and the welfare of the public. But some of the provisions of the measure are urgently called for, and the medical authorities and the profession have seriously to consider whether a continuance of the agitation for reform is not likely to be more injurious than would be the Government Medical Act Amendment Bill were it to become law.

THE NEW PHARMACOPŒIA.

Ten years have passed since the General Medical Council republished the Pharmacopœia of 1867 with additions. The book was then out of print, and to meet the wants of the day "addenda" only were required. Within the space of six years at least one new remedy had come into use. To order a reprint without some notice of chloral-hydrate was impossible; moreover, a fixed strength for the syrup in which it was largely dispensed was much needed. The hypodermic injection of morphia also called for an officinal solution of uniform and definite composition. From time to time a work of this kind must be done, and few will think ten years too short a time for it. Even after an interval of five years some changes have to be noted; after another ten years not only is there new matter to be added, but the time has come for a complete revision. This last epoch is marked by an extension of the germ theory of disease, a larger use of antiseptics, a great increase in germicide agents, and a feeling for local treatment. Hence in our *materia medica* we find oleic acid, the petroleum derivatives, thymol, menthol, boracic acid, and the greatest of our recent gains—salicylic acid. This acid, known since 1838, could not be used largely in medicine, until it was obtained as a derivative from carbolic acid, in 1874, by Kolbe.

Before entering fully into the changes the last ten years demand, it may be well to state the chief objects of revision. These are—(1) selecting and adopting new remedial agents of tried efficacy; (2) fixing the best mode or form for preparing and using them; (3) giving uniformity of strength and officinal position to the forms to be generally prescribed; (4) correcting or amending defects; (5) removing what is or has become useless; (6) avoiding change for the sake of change. Judging the addenda of 1874 by those tests, it would seem that the Horatian maxim—*nonumque prematur in annum*—applied to this kind of literary production. Under the first head areca-nut and larch-bark will hardly stand trial; acetic ether and nitrate of ammonia are little used. Pepsine was not a new agent, it came in to amend a defect; the same may be said of the hypophosphites. Chloral and nitrite of amyl are the only real gains. Under the next head, *aqua chloroformi* is exactly what was wanted, it gives an aqueous solution of full, and therefore, of uniform strength, sufficient to produce some useful effects of chloroform in small doses, and readily diluted for other purposes. The *tinctura quiniæ ammoniata* is a serviceable form. The preparations of phosphorus are open to censure under the third

head. Here scammony and elaterium may be rightly treated, but it was wrong to alter the strength of the widely used *pulvis glycyrrhizæ compositus*, and to leave out two of the ingredients. The fourth and fifth criteria may be applied indirectly; it will then be found that more than half of the thirty-four additions might be removed without much loss to therapeutics.

Foremost among the new remedies to be embodied in the new pharmacopœia stand boracic and salicylic acids; the former required almost entirely for external use, the latter chiefly for administration as salicylate of soda. A solution of boracic acid, in the proportions of one part to thirty of water, is needed; also a glycerine of it, either saturated or like that of carbolic acid; and an ointment that should be uniform in appearance and strength, instead of differing widely in both these respects as do those now in use. The absolute identity of salicylic acid, as prepared by Kolbe's process, with that obtained by Piria, in 1838, from winter-green, justifies the adoption of the former. Individual fancy may dwell on the fitness of salicine from the willow for the cure of ague, or that from spirea and actæa for rheumatism; the objections to prescribing it in the way advocated by the few who use it are, that when taken, it must first be converted into salicylic acid, and then unite with soda in the blood; it is uncertain how much of what we give is so converted, and in what time; we cannot get the full effect soon enough, and we may have a cumulative effect increasing when we wish it to cease. Solutions of salicylic acid with citrate of potash or acetate of ammonia are less definite than the soda salt, which it is hoped will be the officinal form adopted.

Other necessary additions are codeia and pilocarpine. Croton-chloral hydrate should be added, perhaps under its true name of butyl-chloral, for it does not belong to the crotonic acid series. The iodide and bromide of sodium are wanted; but, not the unstable iodide of ammonium. Hydrobromic acid deserves a place. Oleic acid has become a necessity; and vaseline. Menthol is a safe germicide, and is not an irritant. Thymol, as an antiseptic, will often replace carbolic acid. Of the sulpho-carbolates, that of zinc may be chosen; others that have been advocated hardly answer the expectations formed of them as medicines. There is fear lest too many, rather than too few, of the newest claims of old or new agents should be allowed; those of apomorphia, and of the recently prepared chrysophanic acid will need careful consideration. Euonymin, baptisin, leptandrin, and others of the class, may be passed over. An extract of the cascara bark might be admitted. Caffeine should be accepted, but not Lily of the Valley. Sclerotic acid is wanted for hypodermic use; and a tincture of quillaya to prescribe in mixtures with resinous tinctures.

Some points falling under the second and third heads have been already touched upon; there remain two worth noting, a tincture of podophyllin and a powder of colchicum seeds. Podophyllin dissolved in too little spirit deposits some of the resin; a strength of one grain to two drachms, or of five grains to an ounce, might supersede the two tinctures now in use, one of which contains one grain to the drachm, the other one grain to the ounce. The seeds of colchicum are generally more reliable than preparations from the corms or flowers, because they keep well, and the latter cannot often be dealt with while fresh. We use the seeds for the tincture, and should have them in powder; a pill with this and powder of digitalis is widely prescribed, and no doubt should remain that powder of the seeds and not of the corms is intended.

Coming to the fourth head, besides correcting the compound liquorice powder, the old *spiritus juniperi compositus* should be restored; this form recognises that a stimulus to the general circulation often aids a special secretion, and enables us to prescribe a weak spirit, where to order gin would be objectionable; the present *spiritus juniperi* could remain; it is uniform with other spirits, and may serve for the administration of the oil of juniper, when that is desired. The *liquor hydrargyri perchloridi* would be better without chloride of ammonium. The dose of this at the lower limit should be still lower; that for the higher limit of iodide of potassium requires a great increase.

In removing what has become useless more delicate ground is entered upon; no form still in use should be removed without good reason given. It may be well to mention some that are little used, or of doubtful utility, so as to call forth champions who may believe in their virtues to speak in their favour. Who knows anything of elemi? What is the medical efficacy of dulcamara or lettuce? Who uses castor, elm-bark, oak-bark, kousso, serpentaria? Sarsaparilla sometimes does good; it may do less without the sassafrass and mezereon. Bael may be useful as a fresh fruit in India. Lemons and barley are most important aids to treatment, and are rightly in the pharmacopœia. So are the colouring matters, cochineal and saffron. No one now pleads for their soothing or antispasmodic powers. Better retain some harmless remnant of the past, and consent to be old-fashioned, than have to plead guilty to rashness in hastily admitting some active principle just discovered or made that might prove dangerous, *Digitalin* for instance, until it has received careful and prolonged trial.

REVIEWS AND NOTICES OF BOOKS.

MANUALS OF MEDICAL ELECTRICITY.

The use of electricity in the diagnosis and treatment of diseases of the nervous system has increased to such an extent of late years, that any good work on the subject is welcome. The first of the volumes under review, which has found a careful translator in Dr. Putzel, is divided into five parts, delivered in the form of lectures—thirty-six in all—of which the first three are occupied in discussing the physics of electricity. The author by no means dips deeply into this interesting part of his subject, but commences by assuming the reader to be already well acquainted with it, a fact which serves to account for the absence

"Handbook of Electro-Therapeutics," by Dr. Wilhelm Erb, Professor in the University of Leipzig. Translated by L. Putzel, M.D. Sampson Low and Co. 1883. pp. 360.

"A Practical Introduction to Medical Electricity," by A. de Watteville, M.A., M.D. Second Edition, London. H. K. Lewis, 1884, pp. 200.

of certain details and diagrams which one would otherwise have expected at the outset. He touches, however, upon all that is absolutely necessary to make the physical introduction explanatory of what follows. We cannot pass over this part without expressing our cordial agreement with Professor Erb in what he says of the element numerator, the polarity changers, and the galvanometer as accessories of a good battery. We have long held that a reliable galvanometer is a most essential part of a galvanic battery, and that without it there can be no certainty as to the strength of current for purposes of diagnosis or therapeutics; moreover, we all know how batteries vary, from time to time, especially if much used. It would be well if all authors would accept the milliampere as the unit of strength, as it would be of immense service in describing cases, especially when reporting upon the irritability of nerve-structures.

The second part of the volume is taken up with the electro-physiology of nerves and muscles, and is matter which one expects to find in any recent physiological work; but in the third part—devoted to methods of electrical examination and electro-diagnosis—his remarks on "degeneration reaction," a term, it will be remembered, first employed by Professor Erb, are excellent and amongst the best in the book. Each paragraph is carefully and thoughtfully written, and is full of instruction and information. After giving a typical description of degeneration reaction, he adds some important explanatory remarks. Amongst them he points out that in many cases of slight or commencing degeneration there is a form of "double contraction;" upon closure a short lightning-like contraction of the adjacent healthy muscles is observed at the beginning, being followed at once by the slow characteristic contraction of degeneration reaction. This may be distinctly seen in lead palsy. He also mentions the important fact that well marked degeneration reaction is occasionally noticed in muscles which are not at all paralysed, or have only slightly diminished power. In this part his schematic representations are very good.

The fourth part deals with general electro-therapeutics, passing in review the various theories which have been advanced in explanation of the curative effects of electricity. As he considers it possible that the favourable effects of methodical exercise upon the nutrition of muscles is attributable to the fact that every motor irritation is associated with irritation of the trophic fibres, and that the negative processes are thus stimulated, he seems to think that the curative effects of electricity may be explained in a similar manner, but confesses that we are compelled to acknowledge the deficiency of the theoretical basis, and wisely holds that it must be studied on an empirical one. His observations in the thirteenth lecture, on the direction of the current, are most important, owing to the difference of opinion which exists as to whether the polar action or the direction of the current should be taken as the foundation for the method of application. Erb considers, and we agree with him, that proof is still required that the direction of the current is an essential factor in its action. Indeed, there are strong reasons in favour of the polar method, although nothing has been certainly proved. The last lecture of Part IV. is thoroughly practical, containing remarks on, and plates of, the motor points, as well as valuable advice as to the strength of current, the necessity of personal knowledge of the effects of currents, and the duration of sittings.

The fifth and last part, which forms more than half the volume, is, of course, the most important to the practical physician, for it deals with special electro-therapeutics. The introduction to this part is written in a careful and scientific manner. If all work were carried on with the accuracy he desires to obtain, we should be, indeed, fortunate in our literature. We can hardly endorse his views concerning the action of electricity in certain forms of brain disease. The catalytic effects of electrical currents may doubtless raise great hopes of what may be done, and judging from their influence in such affections as chronic effusion into joints, one may believe that hæmorrhagic extravasations, œdema of the brain, and the like, in cerebral disease may be influenced; but in the present state of our knowledge we are not so enthusiastic as to believe that "sclerotic, degenerative, and similar conditions" can be relieved or moderated. The pathology of these affections, we consider, points quite the other way. Even in the external zone of an ordinary sclerotic patch, where we know the degenerative processes are least advanced, the neuroglia is increased in amount, with multiplication of its nuclei, and the nerve-tubes are lessened in diameter at the expense of the white substance of Schwann; whilst in the central area there is hardly anything but neuroglia, most of the nerve-cells and nerve-tubes having disappeared, those remaining being greatly atrophied. Therefore, to cure sclerotic changes, we must cause absorption of condensed material, and restore lines of nervous tissue, or create new ones for the conduction of nervous energy—difficulties not likely to be overcome by electricity. We must always bear in mind, also, that there are many cases of such affections as tabes dorsalis, or disseminated sclerosis, which become arrested without any electrical or other treatment whatever. In his cases bearing on diseases of the brain and cord, there is much of interest, and many of them would bear reporting at greater length. We cannot but think that electricity should be applied to the brain with the utmost caution, for it is impossible to tell exactly in what condition the brain tissue is after hæmorrhage or embolism; therefore the general rules given in Lecture XVI. are most necessary. In the lecture devoted to the treatment of individual forms of spinal disease, amongst others the author mentions compression myelitis where due to Pott's disease, as offering relatively favourable chances, but we must remember that this is frequently recovered from without any treatment whatever, except rest in bed.

In the treatment of lead palsy (which the weight of evidence shows, in his opinion, to be of spinal origin—the primary change taking place in the anterior grey horns) and other toxic paralyses, we are somewhat surprised to find no mention made of electric baths or of the possibility of eliminating metallic poisons by such means. We mention this, as it would have been

interesting in such a work to have had Erb's views on the subject, and any new facts at his command as to the treatment of plumbism.

In the lectures on pain and neuralgia—amongst the best in the book—it is disappointing to learn that he cannot confirm the statements of Frommhold regarding the good effects of electricity in migraine, from which so many suffer, and he, therefore, states that in this respect migraine is distinguished from other neuralgias. The manner in which diseases of the ear are dealt with is excellent, and the small but interesting collection of cases remarkably instructive, and well worthy the serious consideration of aural surgeons.

There are many other points in Prof. Erb's work upon which we should like to have remarked, but in the space at our disposal it is impossible to do more than touch upon some which appear more important. In such a book it would have been useful to have tables for reference—as, for instance, the diseases in which irritability of nerve is increased, those in which it is diminished, &c. A fuller index would also be an advantage. Whilst enthusiastic in some respects, the author is never carried beyond scientific accuracy, as his remarks in numerous places prove. The spirit in which he writes may be gathered from the following: "It is evident we have to deal in the main with empirical methods. I cannot warn you too strongly against illusions based upon theoretical views or against therapeutical illusions founded upon uncontrolled observation. Electro-therapeutic literature swarms with such instances, and the defective criticism of observations has led to immense unsuspected deceptions." After carefully reading through this work, it is refreshing to close it with the belief that the author is conscious of the fact that, much as electricity can do, it is not a panacea for all the diseases to which flesh is heir.

If we have had to allude to the paucity of illustrations in Professor Erb's work, we are certainly spared the necessity of making the same comment in the case of Dr. de Watteville's. The number of woodcuts relating to electrical instruments and appliances contained in the latter, is exactly double the total number of all the illustrations in the former; we are, however, not disposed to find fault with Dr. de Watteville on this account, more especially as he tells us in his preface that he has taken especial care to keep the number of illustrations within reasonable limits. As regards the measurement of electricity, Dr. de Watteville is able to speak of the adoption of the milliampere as the electrical unit as an accomplished fact, and its more general recognition is now only a matter of time. The ampere, we may mention, represents a current conveying the unit quantity of electricity, *i.e.*, one weber during one second. This unit has this to recommend it, viz., that a current of one milliampere is that given by three Daniell's cells through the human body. We have then in this unit a convenient and simple method of measuring and recording the strength of the current used in any given case. Under the head of electro-diagnosis our author enters a vigorous protest against the notion that electrical investigations do not call for special training on the part of those who conduct them. He considers that the fallacies besetting it are far more numerous and subtle than those attending the other methods of physical examination of the living organism. Now, admitting that there is a great deal of truth in what he says, yet it will be well not to push this view too far. Diseases in which the battery is called in, either to aid in diagnosis or for purposes of treatment, do not constitute a very large or important part of the work which the general practitioner will be called upon to perform, and in the education of the student this fact should not be lost sight of. Some excellent advice is given on the use of the galvanometer, and the means by which fallacies in diagnosis may be avoided, and the sections on galvanisation and faradisation furnish admirable and clear descriptions of their respective subjects. In an Appendix, the use of electrolysis in the treatment of nævi, port-wine stains, cancerous and fibrous tumours, cystic growths, and enlarged glands, is spoken of with much favour, one of its chief recommendations being that there is no cicatrisation after the removal of any such diseased condition by this method. In conclusion, we would say that the volume before us is an evidence that its author has had a large experience, and has used that experience well. With these valuable works, as well as the translations of Duchenne's book, and Dr. Hughes Bennett's less pretentious, but, nevertheless, useful volume to choose from, the student of the present day has every opportunity of mastering the principles and practice of this branch of the healing art.

A Manual of Psychological Medicine and Allied Nervous Diseases; by EDWARD C. MANN, M.D. Demy 8vo., pp. 691. Illustrated. J. & A. Churchill, 1883.—The modesty, fairness, and gentlemanly spirit with which Dr. Mann writes, are so pleasing and are in such striking contrast with the tone of other books on psychological subjects that we have recently had to review in these columns, as to produce a very favourable predisposition towards him and his book. The latter is a work of considerable interest and considerable value. It is a most useful book of reference, and one that every student of nervous diseases may consult with advantage. Its merits are due to its mode of construction, which is very peculiar, and indeed altogether unique. Every chapter is introduced by a few statements of an extremely general nature—general in the sense not of generalisations but of generalities. They are descriptions in general terms of the empty shell of some individual case, which has been eviscerated of all its concrete contents. The remainder of the chapter is for the most part composed of quotations from different authors. It is in the length and number of these quotations that the peculiarity of the book consists. Dr. Mann has evidently read very extensively, but instead of following the prevailing practice of reproducing his predecessors' ideas in his own words, he follows the far better and fairer practice of allowing them to speak for themselves. He collects the writings of the best authorities on each subject, and reproduces them *in extenso* in their own words, and of course with due acknowledgment. The result is that each chapter is a symposium on the subject of its title. The generosity with which he yields up his space to others is quite surprising. In his chapter on the Treatment of Insanity, Dr. Pliny Earle is quoted to the extent of six pages of small type. Dr. Gray, of Utica, occupies eighteen pages and a half, eleven of which are devoted to a reproduction of evidence taken before the English Parliamentary Committee of 1877. Dr. McDonald, of New York, follows with four pages, Dr. Kirkbride with eleven, Dr. Cowles with seven, Dr. Maudsley with two, Dr. Ray with four and a half, and a quotation from the Pall Mall Gazette occupies two more. More than half the chapter is taken up by these lengthy reprints, while great part of the remainder is made up of shorter reproductions. The chapter on Epilepsy is made up of seven pages and a half of original matter, and sixteen of

quotations. These reprints, as we may term them, are nearly all valuable, selected with care and judgment, and many of them are taken from sources that are now accessible with difficulty, or not at all. Herein lies the value of the book. Dr. Mann has put himself at a great disadvantage in compelling a comparison between himself and the many eminent men whom he quotes at such length; but even after making great allowances on this score, the part of the book that is written by himself is still open to a good deal of unfavourable criticism, which we would fain have been spared from making: and all the more so since most of the defects that we have to point out might have been avoided by the exercise of a little ordinary care. There is a lack of due proportion in the space and attention devoted to the various subjects. The histology and functions of the entire brain are disposed of in seven pages of a book of seven hundred, devoted to insanity and nervous diseases. On p. 326, the physiology of the corpus striatum is disposed of in three lines, and that of the optic thalamus in two. An entire chapter—not too much—is devoted to General Paralysis, but the etiology of the disease is referred to only in a footnote of three lines and a half. The literary style is bad, often very bad. On p. 88, we read "Her testamentary capacity, although an incurable case of insanity, was perfectly good, and her will perfectly valid." Again, p. 128, "The case just referred to had complained of pains in the head and sleeplessness, which had displayed marked periodicity, and which had been accompanied by great irritability of temper, excited by trifles, &c." Dr. Mann seems unable to make up his mind whether to speak of himself in the singular or the plural; in the event he compromises matters, and speaks as "I" in the text, and as "we" in the footnotes. The numbers of the figures in Plate II, which represent microscopical sections, have got mixed: figures 3 and 5, which are described as sections of brain, being sections of spinal cord. The titles of the figures in the frontispiece, which are photographs of people exemplifying the chief varieties of insanity, appear to have been similarly shuffled. The facial expressions of most of them are not, it is true, in the least characteristic of any form of insanity. The only one which is at all instructive is that labelled "general paralysis," and that is not at all like the face of a general paralytic, but is a tolerably accurate delineation of the expression seen in cases in which chronic melancholia is merging into dementia. Miliary sclerosis is described as a pathological change, no mention being made of the doctrine, now generally accepted, that it is a *post-mortem* change due to the immersion of the tissue in spirit. Regarded as a compendious work of reference, in which the views of many workers can be consulted in convenient proximity, the book is a success; to judge it as an original work would be unfair, since to originality it makes no pretensions.

Insanity considered in its Medico-Legal Relations; by T. R. Buckham, A.M., M.D. 8vo, pp. 264. Lippincott and Co., Philadelphia, 1883.—The author of this book has brought together the dicta of a large number of judges, both English and American, upon the subject of insanity; and the symposium so constituted contains, perhaps, a greater diversity of opinion and more positive contradictions than could be adduced regarding any other topic whatever. The remainder of the volume consists mainly of a plea for the employment, in trials where the question of insanity is raised, of experts who have a knowledge of the subject; and especially for their employment, not by the prosecution nor the defence, but as *amici curiæ*. The argument is somewhat tedious, and much of the reasoning does not apply to the state of things existing in this country. If the author would omit the remainder of the book and republish the collection of judicial dicta in a pamphlet form, he would deserve well of the public.

Poisons: their Effects and Detection. By A. Wynter Blyth. London: Chas. Griffin and Co., 1883.—Mr. Wynter Blyth's somewhat bulky treatise on the effects of poisons and their detection is, as might be expected, addressed rather to chemists and analysts than to practitioners or students of medicine. In his classification of poisons, Mr. Blyth has struck out a new line, and after dismissing the acids and alkalies, discusses poisonous substances capable of being separated by distillation from neutral or acid liquids; he next takes the alkaloids, then poisons derived from living or dead animal substances, then the oxalic acid group, and lastly, inorganic poisons. In his opening chapter, he describes this arrangement as partly chemical and partly symptomatic, and he adopts it on account of its representing, as far as possible, the order in which the chemical expert would search for an unknown poison. Each subject is dealt with in a methodical manner, especial attention being paid to the chemical character and physiological properties of the various substances. One of the most valuable sections of the book is that on the vegetable alkaloids, the methods of separation being expressed in an unusually clear form; and a table of the behaviour of some thirty-six alkaloids, as regards colour, under the influence of certain reagents will doubtless prove useful. The volume concludes with two appendices—one on the examination of blood stains, the other on the immediate steps to be taken in a case of poisoning; and the author winds up with the following aphorism—if any one is known to have taken poison, and yet the precise nature is not known, give a sulphate of zinc or ipecacuanha emetic, and follow it up by the multiple antidote, a mixture containing a saturated solution of sulphate of iron, magnesia, and animal charcoal.

Legal Medicine, Part II.; by Charles Meymott Tidy, M.B., F.C.S. London: Smith, Elder and Co., 1883.—The chief subjects dealt with in this volume are pregnancy, abortion, live birth, infanticide, drowning, hanging, strangulation, and suffocation. The great importance of this group, from a forensic point of view, will be conceded by all; indeed there are, probably, no questions in the whole range of medical practice which raise such difficult points as those respecting live birth. The general plan of the former volume is closely followed out in this one, and the manner in which Dr. Tidy has collected facts from all parts of the world, and extending over a considerable range of time, is worthy of the highest praise. As we noticed the first part at some length, we need only say now that this second part fully justifies the high opinion of the work at which we then arrived.

ABSTRACTS AND EXTRACTS.

PHARMACOLOGY AND THERAPEUTICS.

Transfusion of Blood in Albuminuria.—The *Gazette Hebdomadaire* for January 18th publishes what it regards as a very important paper, bearing this title, read by Dr. Dieulafoy, of the St. Antoine Hospital, at the Hospital Medical Society. He first draws attention to the remarkable fact that the lives of persons dying from hæmorrhage have often been saved by the injection of so trifling an amount of blood as 100 or 150 grammes; and he relates a case in point, in which a person dying of an epistaxis which resisted every measure resorted to during 20 days, was at once rescued from danger by the transfusion of 120 grammes of healthy blood. Such a case as this, however, differs from those cases of traumatic hæmorrhage (consecutive to operations or to delivery) in which the cause is purely accidental, for it is brought about and maintained by an altered condition of the blood, of an ill-defined nature, termed for want of a better name *hæmophilia*—a dyscrasic condition in which perhaps the structure of the small vessels is at fault, but in which the blood certainly is no longer possessed of its normal properties. Life has been saved by transfusion in several cases of this kind, not merely because the blood supplies an additional amount of fuel to an expiring lamp, but because it plays the part of an agent which is to some extent hæmostatic. The addition of so small a quantity of healthy blood serves to modify advantageously the composition and fabrication of the blood that seems to have lost its principal qualities. "In such a case," Dr. Dieulafoy observes, "the infused blood acts, I repeat, as a hæmostatic agent. It is a powerful modifier, rapidly transferring a

dyscrasic condition of long date by a special action, the mechanism of which is as yet but ill-known, but with a result well calculated to attract attention. All the importance of these facts, which seem to me to dominate the history of transfusion, has not yet been sufficiently brought out. A closer investigation of them has led me to ask, like many others for that matter, whether there is not reason for the applications of transfusion to some dyscrasic conditions in which alterations in the blood seem to play an important part. May not dyscrasic hæmorrhages, uræmia, and Bright's disease, diabetes, and acetonæmia, the paroxysm of gout and rheumatism, derive benefit from this modifying agent, the effects of which we are as yet ignorant of, because they have not been sufficiently investigated?" In order to render an extended theraputic application of transfusion possible, Dr. Dieulafoy has contrived an apparatus, which he believes will much simplify and facilitate its application. An illustrated description of it, as laid before the Académie de Médecine, is contained in the same number of the *Gazette Hebdomadaire*. In the present paper he relates three cases of Bright's disease in which transfusion was performed; but he admits that nothing conclusive can be decided from them. They however establish the innocuity with which injections of 120 grammes of blood may be performed, even in the later stages of Bright's disease; and also the temporary amelioration that may be obtained, even when the lesions are of the most formidable character.

Quebracho in Asthma.—Professor Da Costa has had some very satisfactory results from the treatment of dyspnœa by quebracho. In a recent lecture he said that in his experience it had been especially serviceable in two classes of cases. 1. In purely nervous asthma he had found it to be invaluable. 2. In cases which have been rather loosely called cardiac asthma, cases in which a heart lesion has produced failure of cardiac contraction and consequent congestion of the lungs, he had also known it to be very useful. It may serve as a cardiac tonic, or may do good solely by its action on the respiratory centre in the medulla. Whatever be the explanation, however, quebracho gives relief in appropriate cases. Dr. Da Costa gives it in the form of the fluid extract in doses of twenty minims every hour, gradually increasing the amount, some patients requiring as much as a drachm before relief is obtained. The good effects are usually observed after two or three doses have been taken. The taste is well covered by using equal quantities of French syrup of red oranges and water as the vehicle, and in this form it usually agrees with the stomach. As the symptoms are relieved, the remedy may be given at longer intervals.—*Boston Medical Journal*, December 27th.

Alum in Hæmaturia.—A case of severe hæmorrhage from the kidney successfully treated by an unusual remedy, is recorded by Dr. J. S. Radcliffe, in the *Philadelphia Medical News* for January 12, 1884. The cause of the hæmaturia is left an open question. It is stated that the patient, a lady, aged twenty-five, had suffered from malarial disorders, and that there was a family history of heart disease and rheumatic fever. At the time of the attack, however, the temperature was but slightly raised, and the heart sounds were normal. Although the hæmaturia came on suddenly, with paroxysmal pain in the right lumbar region and with nausea, it is curious to note that the urine remained bloody for nearly three weeks. During this time, almost all the astringents were tried with no beneficial effect. The patient was first given gallic acid alone, then in various combinations, the acid with quinine, with ergot, with sulphuric acid, with opium. She also took tannic acid, sugar of lead and opium, fluid extract of ergot, infusion of buchu and matico, muriated tincture of iron, and with this quinine; extract of logwood, and extract of hamamelis. Ice was employed internally and externally, and counter irritation, by sinapisms and blisters, was used. The hamamelis appeared to lessen the hæmorrhage slightly, but for the rest, Dr. Radcliffe says "it appeared as if I might as well have given her so much cold water." Rockbridge water was then used on theoretical grounds, champagne-glassful draughts being taken every three hours. Beneficial effects were manifested with the third dose, and on the fourth day the urine was free from blood corpuscles, and on the sixth day it was normal in colour, quantity and quality. It merely remains to add that the Rockbridge alum water appears, from an analysis appended to this paper, to be remarkably rich in aluminium sulphate, and to contain very appreciable quantities of calcium and magnesium sulphates, free sulphuric acid and cilicic acid. It is said to have been employed with benefit in chronic discharges, such as diarrhœa and bronchorrhœa.

Administration of Salicylic Acid.—The apyretic effect of salicylic acid is one of the most remarkable and important therapeutical discoveries of our age, and its control over all such conditions as are generally met with in acute and subacute rheumatism is almost complete. Its applications, therefore, in medicine are very numerous and very important. In its internal use, the points necessary to be borne in mind are the disturbing effects of very large doses, and the rapidity with which it is eliminated. It should, therefore, be given in full doses at first until the impression is made, and then in moderate or small doses, frequently repeated. It is best given in wafers or cachets, and it should not be packed in capsules. Two or three doses of fifteen to twenty grains, with two or three hours intervals, will usually produce its characteristic beneficial effects. Then ten grains every two hours, with intervals, gradually increasing to three and four hours, will serve to keep up the effects with the smallest risk of such disturbance as will require it to be suspended when most needed. Of late it has been more rarely used, the salicylate of sodium having taken its place with the same effect, and with some advantages. It is a curious and very important circumstance, that full doses of the acid or salicylate do not interfere with the digestive functions of the stomach, and yet a very small quantity will prevent the action of pepsin. At least this statement is made on what appears to be very good authority. An ordinary cold saturated solution contains somewhat about one part in 300; and such a solution is very convenient as a vehicle of solutions of alkaloids for hypodermic use. If a dram of the acid be added to a pint of water and the mixture well shaken, such a solution, with some undissolved acid at the bottom of the bottle, will be the result. Then, if this be used entire, or diluted with an equal portion of water, for making hypodermic injections, such a solution will remain free from growths of all kinds for an indefinite length of time, and will not be more irritant than when made from water alone.—*Squibbs' Ephemeris.*

Resorcin in Pertussis.—Another remedy has to be added to the hundreds already known for pertussis. Dr. Moncorvo, of Rio Janeiro, in a communication to the Paris Société de Médecine, fully believing in the parasitic origin of pertussis, recommends the employment of an aqueous solution of resorcin (one per cent.) carried by means of a soft pencil with a long handle to the superior orifice of the glottis. Resorcin is more soluble, less irritating, and much less odorous than carbolic acid. He has applied the remedy in 30 cases every two hours during the day-time, and in all of these recovery was rapid.—*Turin Méd.*, February 5th.

Disguising the Smell of Iodoform. — Dr. Leidy, writing in the *Philadelphia Medical Times*, December 15th, observes that the best substance that he has met with for disguising the odour of iodoform is *oil of citronella*, which, unlike many substances employed for this purpose, has the further advantage of being very cheap. Two drops to a drachm are sufficient. It may also be added to cod-liver oil for the same purpose, when this is used externally. The citronella oil itself, when used externally, is a rubefacient and anodyne, and may be employed either alone or in combination.

Salicylic Acid Paste in Eczema.—Dr. Van Harlingen recommends the following:—Acid. Salicyl. gr. xv., Petroleol. ʒiv., Pulv. Zinci Oxidi, Pulv. amyli, aa ʒii. Rub up into a smooth paste.—*Philadelphia Med. Times*, December 15th.

Strychnia in Delirium Tremens.—Dr. Dujardin-Beaumetz (*Bulletin de Thérapeutique*, January 15th), while disagreeing with the opinion of Dr. Luton, of Rheims, that strychnia is the appropriate medical agent for combating alcoholism in general, is quite in accord with him as to its great value in the treatment of *delirium tremens*. In this it is one of the most certain and efficacious of remedies which he has successfully availed himself of in many cases at the St. Antoine Hospital. He administers it in hypodermic injections, beginning with a dose of five milligrammes, which he repeats in five hours. Sometimes, if the symptoms persist, he gives a third injection within the twenty-four hours.

Patent Medicines.—The Philadelphia correspondent of the *Boston Medical Journal* writes (January 17th) concerning these:—"The leading druggists of this city, becoming disgusted with the patent medicine traffic, have decided, after the 1st inst., not to deal in those proprietary medicines which are sold as merchandise to non-medical dealers. It is now, and has been for some time, indeed considered very bad 'tone' for a scientific pharmacist to exhibit patent medicines in show cases, or to have their lying placards hung up in the store; much less would one of the principal apothecaries think of assuming the responsibility of recommending articles of whose composition he is ignorant. The druggists all over the country are alive to the evil, which has grown to such proportions as to seriously threaten the future of legitimate pharmacy. Fortunately, the public has acquired a healthy scepticism with regard to advertisements of panaceas, even when they appear in religious papers and are endorsed by clergymen and members of Congress. How soon will this country attain to the degree of civilisation of Japan, and appoint a Government Commission to examine all patent medicines that are offered for sale, and publish the formula on each packet sold? We do it with guano: why not with cough-syrups?"

Boracic Acid.—At a meeting of the Vienna Medical Society, Professor Rosenthal observed that boracic acid is little soluble in water (one to 26), but that a solution in hot glycerine (one to five) can be kept a long time without any fungus formations taking place. In cases of ammoniacal cystitis, in which balsams and turpentines are useful, but exert a mischievous effect upon the intestinal canal, as do also salicylic and benzoic acids, and in a slighter degree chlorate of potash—boracic acid given in doses of from one to one-and-a-half grammes per diem acts as a mild acid and a good antiseptic, the urine at the end of several days becoming acid and free of bacteria. If two grammes are combined with 100 of water, and some glycerine or syrup of orange-peel is added, the patient will bear this daily dose for weeks, the bladder being washed out also with a two or three per cent. solution of the acid.—*Allgemeine Wiener Medicinische Wochenschrift*, January 15th.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, March 11th, 1884.

George Johnson, F.R.S., President, in the Chair.

Two interesting papers were communicated. The following are abstracts, with the discussions which ensued:—

Fourth communication on artificial respiration in stillborn Children. Certain minor points. An experimental enquiry.

By Francis Henry Champneys, M.A., M.B. Oxon, F.R.C.P., Assistant Lecturer on Midwifery and Assistant Obstetric Physician to St. George's Hospital.

1. The effect produced by the presence of air in the abdominal viscera on the amount of air capable of being drawn into the lungs by the manipulative methods was tested. A cannula was tied into the navel of a stillborn child so that the abdominal cavity could be distended at will. Moderate or even extreme distension of the abdomen produced no effect on the amount of air inspired.

Conclusion.—The presence of air in the abdomen (*e.g.*, in the stomach and intestines) in no way impedes the ventilation of the lungs by artificial respiration. N.B.—Its effect on natural respiration is another matter.

2. Certain methods of preventing the entrance of air into the stomach in mouth-to-mouth inflation were then tested: (*a.*) by pressing the cricoid cartilage against the spine; (*b.*) by strongly bending the head back.

Conclusion.—Both methods are powerless to prevent the entrance of air into the stomach while allowing it to enter the lungs (in infants).

3. The condition of the upper air-passages (as to patency) when the head was strongly bent back was tested by a sagittal section of a stillborn child frozen in this attitude.

Conclusion.—The soft palate lay against the back of the tongue over a large extent. This attitude, therefore, cannot be trusted to secure patency of the upper air-passages.

The great difficulty is probably lower down; it is suggested to leave a catheter in the trachea during artificial respiration, which will serve for the escape of mucus as well as for securing the patency of the air-passages. It may be secured by an elastic band at the proper length (three and a half inches from the lips).

4. An improved method of removing mucus from the air-passages is given.

5. The signs of returning life in a deeply asphyxiated child are given from a careful observation.

Dr. Matthews Duncan said that he had noticed an improved colour, with a fuller and more rapid pulse, take place before any respiration occurred. He then enquired whether Dr. Champneys had observed a double form of respiration in these cases—first a violent spasmodic breathing, "the asphyxia breathing;" then, shortly afterwards, the ordinary rhythmical, and how these two forms alternated for a while, before the ordinary form of breathing was fully established. The use of a catheter, he said, was very old, but it appeared to have been given up; why, he could not say; among students, it probably was inefficient, on account of being passed into the œsophagus instead of the larynx. He should not have thought that repletion of the abdomen would have been found to exercise so little effect on the amount of air inspired. In pregnant women, as was well known, there was no interference with the respiratory function, but in them what the chest lost in one direction it gained in another.

Dr. Bowles said that when the Marshall-Hall method was first introduced, great expectations were formed of it. He had had two opportunities of examining fœtuses in which the method had proved quite insufficient, and he had since thought that the reason for this was to be found in the fœtal tissues themselves; they were very soft and flabby—not unlike wet paper—the ribs had no elasticity, and hence could not do the share of work that was expected of them, and on which the plan depended. Then there was no pharyngeal cavity, and he had been interested in learning how Dr. Champneys got over the difficulties which this fact entailed. In his own opinion, he thought that respiration in such cases could only be brought about by some reflex action, and he agreed with Dr. Duncan as to the changes in appearance in the infant which preceded actual respiratory effort. The heart might beat well and for many minutes without any respiration. In the Marshall-Hall method, pressure on the chest was further useful by assisting the circulation of the blood through the cavities of the heart.

Dr. Powell thought that the manometer was only useful in a qualitative sense, and in no way as a quantitative measurement of the inspired air in such experiments; the lung being completely collapsed and airless, its natural elasticity never came into play. He doubted whether the breathing

of a pregnant woman were comparable with the abdomen artificially distended with air.

Dr. SYLVESTER remarked that in all forms of artificial respiration, the difficulties lay in making *a start*. Dr. Champneys' idea that the difficulties lay in the upper air-passages was, in his opinion, disproved by the fact that even after all impediments had been removed, there were cases in which it was impossible to do artificial respiration. He questioned the possibility of reflex action in dead bodies.

Dr. CHAMPNEYS briefly replied. He had noticed the acceleration of pulse, and the double breathing referred to by Dr. Duncan. The use of the catheter was very old, he knew; yet its permanent retention in the larynx during the whole period of artificial respiration was not as much insisted upon as it ought to be. In the case of profound asphyxia pressure on the chest could do no good, for it was impossible to get more than negative pressure.

On the Value of Systematic Examination of Stillborn Children.

By J. B. SUTTON, Lecturer on Comparative Anatomy at the Middlesex Hospital School of Medicine.

The object of the paper is to show that much valuable information may be gained by the systematic examination of stillborn children, as illustrated by a few selected cases possessing more than ordinary interest.

The first case is an instance of recent endocarditis occurring in an eight months' fœtus. The pulmonary and aortic valves showed soft recent vegetations, and one curtain of the mitral valve was exceedingly puckered. There was general anasarca, and the pleural, pericardial and peritonæal cavities were distended with fluid. Mother healthy, no rheumatism, &c. "Is the case an instance of disease attacking the fœtus independently of the mother?"

The second example is a case of complete stricture of the duodenum above the entrance of the common bile duct; the specimen is described at full length, and observations are recorded to show that stricture, met with in fœtuses at this spot, are not due, as is supposed by certain authors, to hypertrophied valvulæ conniventes, for these foldings of the mucous membrane "do not arise until just before birth."

The third specimen is that of a fœtus with lateral curvature of the spine, and arrested development of the upper limbs. Other cases are quoted, and the question occurs as to the relation (if any) between congenital curvature of the spine, and arrested development of the upper limbs.

One example of single kidney, and two cases of cystic diseases of these organs are described; one of the cases showed conclusive evidence of peritonitis resulting in adhesions between the kidney and testicle, preventing the descent of that organ.

A fœtus with congenital deficiency of one half of the diaphragm is among the cases of interest. The left lobe of the liver passed into the pleural cavity, the lung of that side being in a very rudimentary condition.

A sphenoid bone removed from an immature fœtus exhibited a deficiency of the floor of the pituitary fossa, so as to allow of meningocele in this situation bulging into the pharynx.

In addition, a new explanation is offered of the occurrence of meningocele and encephalocele in the occipital region of the skull. From the third to the end of the fourth month, sometimes even well into the fifth month of intra-uterine life, there exists a "membranous space," which extends from the foramen magnum well up to, and at the third month even into, the point of confluence of the four centres of the squamo-occipital bone. At the fourth month this "temporary occipital fontanella" begins to suffer obliteration through the growth of a bony spiculum, which extends from the squamo-occipital bone gradually downwards to the foramen magnum.

The following is urged as a more satisfactory explanation of the occurrence of meningoceles in this situation than that previously offered: "through this temporary fontanella hernia of the membranes of the brain probably occurs very early in intra-uterine life."

In conclusion, it is urged that without doubt much information may be obtained concerning hereditary diseases, if the bodies of stillborn children be *systematically* examined.

The PRESIDENT remarked on the interesting nature of the communication, and on the great value which such observations possessed. As regarded the heart affections, he had been struck with the rarity of endocardial lesions, on the right side of the normal heart, while in cases of malformed heart, such lesions were equally common on the two sides.

Mr. LOCKWOOD thought the subjects discussed in the paper divided themselves into two classes of cases: the first being arrests of development, the other being pathological conditions. He had met with many cases of intra-uterine peritonitis: this condition was doubtless often concerned in undescended testis. The descent of the testis had an intimate relation with descent of the colon; and absence of the colon from the right loin was often associated with undescended testis, and was, he thought, due to intra-uterine disease. He referred also to cases of obliteration of the descending aorta, a curious and unexplained condition, but which was not necessarily a fatal condition. If we were to draw any practical conclusions from such observations, it would be necessary to know something about the family history of the fœtuses examined.

Mr. SHATTOCK considered the presence of the occipital fontanelle, to which attention had been directed by Mr. Sutton, as having an undoubted bearing on the occurrence of occipital meningocele; it had, by Harvey, been termed the anonymous fontanelle. But, he thought, there was another element determining the seat of meningocele generally, cerebral or spinal; and it was the mode of ossification. Such protrusions occurred between the parts of a bone, or between bones formed in cartilage, or between such and a membrane-formed bone. In the case of the occipital, the deficiency extended between the lower halves of the squama, which are formed in cartilage, and was limited by the seat of the protuberance. In fact, in the case of cartilage formed bones the ossification was limited to the cartilage-basis, and separation of the parts was effected without any corresponding increased bone-formation; hence a gap resulted, as in the occipital deficiency and in the neural arches in spina bifida. In the case of membrane-formed bones no such precise limitation occurred; and if the protrusion occurred, say through the anterior fontanelle, the ossification extended in the wall of the protrusion, and a deformed skull resulted, comparable to those produced by artificial pressure. With regard to the specimen of absence of one kidney, it needed to be determined whether the organ was from the first wanting, or whether it atrophied and disappeared owing to some pathological lesion. He knew of a specimen of a fœtus at full term in which the left kidney was a flattened mass no larger than the little finger-nail, and this might evidence a link in the case of complete absence.

Dr. O'CONNOR thought the valvular lesion might be syphilitic, just as well as rheumatic.

Mr. SUTTON replied: the absence of any syphilitic lesions in the other children, he thought, excluded syphilis as a cause in the case referred to. Mr. Shattock's observations were important, and would receive consideration. Mr. Lockwood's criticism was just, but he thought his former observations confirmed, rather than otherwise, the value of examining all fœtuses.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The Lord Mayor, supported by Lord Shaftesbury, the Dean of Llandaff, Cardinal Manning, Mr. John Marshall, and others, will preside on Friday, the 21st, at a meeting at the Mansion House in aid of the completing the rebuilding of the above hospital.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

FRIDAY, FEBRUARY 15TH, 1884.

Dr. DUDFIELD, President, in the Chair.

The Examination of Water for Sanitary Purposes.

A PAPER on this subject, of considerable length, was read by C. CASSAL, F.I.C., F.C.S., and B. A. WHITELEGGE, M.D., B.Sc. The authors, after alluding to the fresh interest attaching to the subject, in consequence of the suggestion of entirely new methods of examination, founded on the detection and cultivation of organisms, said that the aim of the analyst was to determine the presence or absence of impurities, and the nature and quantity of those present in the particular sample, and then from these facts to form an opinion, so far as this was possible, as to the wholesomeness or otherwise of the water supply. The old plan of exactly estimating the several mineral constituents of the residue was for sanitary purposes quite useless. The organic was the matter of greatest moment to the sanitarian, but its exact determination presented great difficulties. The various methods proposed were all referable to one of two classes, viz., those which aimed at its estimation in the water itself, and those which did so in the residue. Confirmatory evidence was afforded by the presence of nitrates derived from the oxidation of nitrogenous organic matter, by the presence of chlorides, which invariably accompanying animal pollution, nearly always indicated the presence of sewage, by microscopical examination too frequently neglected, by colour, &c.

Of the processes employed for determining the organic matter in the water itself, two were in general use, viz., the *Oxygen or Permanganate Process*, which aimed at a measurement of the amount of pollution by the rapidity and extent of the decomposition of a weak solution of permanganate of potash, acting on the oxidisable matter present, and the *Wanklyn Process*, which made the amount of ammonia evolved, on boiling with a strongly alkaline solution of permanganate of potash, a measure of the quantity of nitrogenised organic matter. The chief process dealing with the dry residue was that of Frankland and Armstrong, in which the nitrogen and carbonic acid, evolved in its combustion with cupreous oxide, were taken as the measure of the nitrogen and carbon contained in the organic matter.

The oxygen process, as originally devised by Forchhammer, was far from trustworthy, though as now improved it afforded valuable confirmatory evidence. But the authors decided to confine their attention to the two processes: Wanklyn's and Frankland's—of which the former was certainly the more popular—and which were very generally looked on as rival and antagonistic. But the truth was, as Dr. Cornelius Fox had shown by comparing a hundred analyses, that in skilful hands the results were practically identical.

Certain objections had been raised against each. It had been asserted that the long process of evaporation with sulphurous acid, probably involved the loss or destruction of some of the organic matters, especially of the more volatile, which had been on purely hypothetical grounds held to be the most dangerous. It could not be denied that such loss might occur, but its amount was quite unimportant, and there was no proof whatever of its specially dangerous character. Again, it had been alleged that the errors of experiment might exceed the total amount of organic carbon or nitrogen present, and that an excess of nitrates altogether vitiated the result. This was an unfairly exaggerated estimate of the difficulties attending the process, although the liability to error was certainly greater than in similar procedures. Against Wanklyn's method it had been asserted that the whole of the nitrogen was not converted into ammonia, and that the quantity obtained was affected by the concentration of the water, and the rapidity of boiling. But Mr. Wanklyn had all along insisted on the fact that only a part, though a nearly constant proportion, of the organic was thus converted, and protested against the practice of those analysts who returned it as representing the "organic nitrogen" present. Any opinion as to the character of a water, based on an estimation of the organic nitrogen and carbon, or of the free and "albuminoid" ammonia only, to the neglect of the chlorides, nitrates, microscopical examination, &c., was, the authors repeated, utterly worthless. The estimation of the nitrates should never be omitted, though it was possible that Dr. Frankland attached an exaggerated importance to them.

But the value of water analysis generally had of late been called in question, Dr. Buchanan, for example, having stated his belief that "we must go beyond the laboratory for evidence of any drinking water being free from dangerous organic pollution," and that "the chemist can tell us of impurity and hazard, but not of purity and safety." It had been alleged that where the absolute and relative amounts of impurity had been previously known, both Frankland's and Wanklyn's processes had given results very far from the truth, and by some that cultivation methods were destined to supersede chemical analyses, and that in short, as Dr. Angus Smith puts it, "water analysts must be prepared for a new order of things." As regards the first of these objections, it was perfectly true that there was a limit to the quantity of organic matter that analysis could detect, and it could not distinguish between living and dead matter, or between noxious and harmless, specific and non-specific organisms. A minute quantity of enteric stools would be more dangerous than a large amount of healthy ones, just because they were enteric, and the chemist could only state the actual quantity. But he could tell us that the water was polluted and where non-specific pollution was present, specific might be so too, and even if it were not, putrefaction might render the "innocent" pollution dangerous. Dilute sewage might be under circumstances drunk with impunity, but it could never be considered safe or desirable. That a quantity of a specific poison too small to be detected by analysis might exert its pathological effects could be denied, and in these rare cases it was much to be desired that we could "go beyond the laboratory" and perform a physiological experiment, but as a matter of fact such specific organisms were rarely ever if present without a large amount of other organic pollutions.

The only well-authenticated instance of this kind, but one which had been eagerly seized on as if of probably frequent occurrence, was that of the well at Caterham, where a man suffering from enteric fever had been at work, and in which he confessed to having defecated. The circumstances were ably investigated by Dr. Thorne-Thorne, who traced beyond question to the mingling of the water from this well with the general supply 200 cases of enteric fever which occurred within a fortnight of one another. But conclusions of an utterly unjustifiable nature had been drawn from it, and might be found stated in the report of the medical officer of the Local Government Board for 1881–1882, as that the excreta of this man were uniformly distributed through the 1,861,000 gallons of water pumped from this well during the fortnight, and that, even on the absurd assumption that the man evacuated nineteen pounds of fæces daily for the fortnight, there would consequently have been but one grain per gallon of enteric stools in the water in question, a quantity which Dr. Cory found by experiment would yield only 0·014 parts per million of albuminoid ammonia, and be insufficient to remove the water from the class of "extraordinary purity." It was far more reasonable to suppose, in the absence of any analyses of the samples of water that did actually communicate the disease, that the solid fæcal matters were not thus equally distributed, and that the water which propagated the fever would have been found to contain much more than a grain in a gallon. Dr. Cory, from a series of carefully conducted analyses of the Lambeth water, to which he added known quantities of egg albumen, healthy or enteric stools, came to the conclusion that when the polluting matters were of the same kind, and not in great amount, Wanklyn's process gave very fair indications of the proportion of the polluent present in each case, but that it failed to show the relative proportions when the quantities of the same matter were very large, or when the organic matters were of divers kinds, some yielding a far larger proportion of albuminoid ammonia than others, the difference depending on the chemical composition of the polluent, and on the relative proportion of

soluble and insoluble constituents, and Dr. Cory considered Wanklyn's classification of waters, founded on their yield of albuminoid ammonia, as highly unsatisfactory.

As to Dr. Frankland's process, Dr. Cory considered that it more fairly achieved all it professed to do. But some of Dr. Cory's analyses seemed so much at variance with the generally received opinions as to the merits of water analyses, with the almost exact agreement of the results obtained by Wanklyn's process in the hands of different chemists, operating on the same water, with Wanklyn's own experiments, and also with Dr. Cornelius Fox's comparisons of Frankland's and Wanklyn's processes, that the authors were inclined to believe that the discrepancies must have been due to the neglect of certain precautions, as those ensuring uniformity of composition in the polluent, and its uniform distribution through the water, the accurate standardising of the reagents, &c. Mr. Cassal and Dr. Whitelegge accordingly instituted a course of experiments on waters containing known quantities of various polluting matters. In all such enquiries it must be borne in mind that such pollutions as enteric stools were composed of solid matter, that only a part of this was nitrogenised, and only a part of the nitrogen might come off as ammonia. The albuminoid ammonia was not an absolute measure of the bulk or weight either of the polluent or of the solid matter in it, or of its properties whether dangerous or not, or of the absolute amount of nitrogenised matter, or of the nitrogen in organic combination (which Frankland's process does profess to show), but the authors ventured to maintain that it did present a constant proportion for varying quantities of the same polluent, and that under all ordinary conditions the limit of 0·15 parts per million of albuminoid ammonia, based on a long series of experiments, might be considered a safe one, other circumstances being taken into account, while anything approaching this proportion was enough to arouse suspicion. As to its inability to measure the differences between high degrees of pollution, it was obviously unfair to expect a process capable of distinguishing between one and two parts to do so with equal accuracy between 52 and 53, and an error of one part, which in the one case would be 50 per cent., would in the other be only two per cent.

As to Dr. Cory's experiments on water to which fæcal matters had been added, it appeared that he did not always determine the proportion of dry solids or of soluble to insoluble substances. Again, it was manifestly unsafe to assume a uniform composition in every part, even of the same stool; and when the water had been allowed to stand, and the suspended matter to subside, one had no guarantee that the pollution was equally diffused throughout the supernatant and comparatively clear fluid. Such experiments were always open to doubt, though they were important from the frequency and gravity of fæcal pollution. Next as to urea, Wanklyn had shown that, being a fully oxidised, i.e., not an oxidisable organic body, it did not yield "albuminoid ammonia," though, if allowed to decompose and undergo transformation into ammonium carbonate (and in practice this change was always far advanced), it appeared as free ammonia, but meanwhile it would be vain to look for uniform results. In one experiment Dr. Cory spoke of urea having passed into some form yielding albuminoid but not free ammonia, a conclusion which must be erroneous.

Experiments with egg albumen were not so liable to error, though after a time the solution tended to become opalescent and unequal, however carefully mixed and filtered at first. The authors also found egg albumen prone to cling to the sides of the flask in the act of coagulation, still their results, as well as Dr. Cory's, never showed any material error. They believed, however, that the natural organic pollutions were better and more accurately determinable than artificial ones, for they had always found that in operations on equal quantities of the same water, they had obtained like results in successive experiments, and proportional results when using different quantities, all other conditions being the same. The serious discrepancies in some of Dr. Cory's experiments must, they thought, have been brought about by his having used quantities of polluent widely differing from what occurred in ordinary waters, and also from his using a water already impure as a diluent.

Whatever future might be in store for cultivation processes, the authors did not think that they afforded at present any information that could not be as well obtained more easily.

Dr. Cory, while preferring on the whole Frankland's process as performing nearly all it professed, made an exception as regards urea, for since 3·094 grains per gallon gave no increment of the total solids in Trafalgar-square water, it must have been decomposed and dissipated during the evaporation. It had, therefore, the authors thought, no advantage over that of Wanklyn's, which, if properly worked and accompanied by the other estimations to which they had referred, gave quite as good a distinction between animal and vegetable impurities, while there could be but one opinion as to the greater manipulative skill required by Frankland's and the liability of its results to error in inexperienced hands.

Dr. THURSFIELD remarked that though the name of Mr. Wanklyn was generally associated with the albuminoid ammonia process, he knew that Mr. Wanklyn attached at least as much weight to the so-called moist combustion method. He had himself performed, perhaps, more water analyses, which had been the bases of legal proceedings, than any man, and he considered Wanklyn's processes quite accurate enough for their purpose; but he maintained that the evidence of analyses might condemn a harmless water and permit the use of one highly dangerous from specific polution, and he denied that the Caterham case was by any means an isolated one, several having come under his personal notice in which waters, pronounced on chemical grounds to be pure, had been proved by statistical enquiry and by their physiological effects to have been the means of spreading disease, and even the fact and manner of their contamination had been discovered.

Dr. T. STEVENSON expressed himself doubtful as to the value of microscopic examinations, and especially called attention to the fact that the "sewer fungus," so-called, although an alga, not a fungus, was constantly found in thermal springs.

Mr. WYNTER BLYTH considered that the authors of the paper laid too much stress on single factors, and called the attention of the members to the numerical scheme for estimating the value of any given water, provisionally authorised by the Society of Public Analysts. He had not succeeded in repeating Koch's methods, and preferred sterilised broths to gelatine. He had frequently observed the development of the sewage fungus in waters kept for 24–48 hours in an incubator; it sometimes appeared in such as were considered pure on other grounds, but always in the impure and in those to which a little sugar had been added. He demurred to any conclusions being drawn from Dr. Cory's experiments on the clear fluid from a fæcal infusion on account of the very unequal distribution of bacterial clouds in a liquid.

Dr. TRIPE objected to judgments on waters being based on chemical analyses alone, since these failed to give any idea of the condition in which the organic matter exists, a fact of far greater importance than its quantity, and referred to his report of an outbreak of diarrhœa, &c., of a severe character attacking all, whether residents or visitors, who drank the water of a particular main at Stamford Hill without boiling, and no others. The water was analysed and pronounced pure by Mr. Wigner, but a quantity of a peculiar mycelium was found in the main. He protested against the low value attached to the microscopical examination in the scheme alluded to, though living organisms merely indicated the presence of organic matter on which to feed, and need not be themselves injurious. He was much surprised at Dr. Buchanan's assumption, that the enteric stools were uniformly distributed through the whole of the water supplied by the well at Caterham during the entire period of the outbreak, believing that it was more probably confined to that distributed on the first day, perhaps even the first few hours only.

Mr. CASSAL and Dr. WHITELEGGE replied to several criticisms, the latter remarking that though the microscope could not as yet distinguish the various kinds of bacilli, it might frequently, by revealing fragments of tissues, point to the nature and source of pollution.

THE WEST LONDON MEDICAL CHIRURGICAL SOCIETY.

FRIDAY, FEBRUARY 1ST, 1884.

DR. THUDICHUM, President, in the Chair.

Amputation through the Joints of the Lower Extremity.

MR. KEETLEY showed cases of amputation through the knee-joint, of Pirogoff and of Hey's amputation; and he also showed (by permission) the patient in whom the late Mr. Shuter had disarticulated at the hip, sub-periosteally. Mr. Keetley contrasted the chief arguments for and against amputating through the joints of the lower extremity. When a distal segment of bone was left, *e.g.*, in Pirogoff's and in Gritti's amputations, he strongly urged that it should be wired to the proximal bone; and he showed that, otherwise, it usually became retracted and a source of tenderness in the stump.

Mr. LUNN dwelt upon the necessity of leaving the periosteum in all cases.

Mr. THOMPSON spoke in favour of the Beaufort limbs, especially as regards their light weight.

Mr. BENTON asked Mr. Keetley if it was his custom to save the patella when amputating at the knee-joint; and also asked his opinion as to which was better: to make a long anterior flap and short posterior flap, or *vice versâ*; remarking that he himself had found that the long anterior flap was often attended with much sloughing.

Dr. THUDICHUM enquired Mr. Keetley's opinion as to the exact fate of the cartilage in the case of a successful amputation of the knee-joint, and remarked upon the advantages of wiring the stump, as it afterwards became the more serviceable.

In reply, Mr. KEETLEY said that he thought the artificial limbs lately exhibited by Mr. Thompson, viz., the Beaufort artificial limbs, might be well adjusted to a patient whose hip had been disarticulated, if only it were, made to take a firm hold of the pelvis. An artificial limb for an amputation at or near the hip, should make use of the pelvis, exactly as an artificial leg, for an amputation at or near the knee, used the thigh. With regard to saving the patella, he was opposed to it unless a Gritti's amputation was done, and the freshened surface of the patella applied to the sawn surface of the condyles. He believed the changes in the cartilage, after a successful disarticulation, were identical with those which occurred in cases of unreduced dislocation.

General Paralysis of the Insane—A doubtful Case.

Dr. J. ALLDEN OWLES reported on the progress of a case brought before this Society in April last, by Dr. Drewitt, who showed it as a case of "General Paralysis of the Insane;" but at the meeting, Dr. Forbes Winslow and others thought it a case of simple aphasia, which would probably pass off in about six months. The patient shortly showed signs of improvement both in walking and speaking, and obtained a position as butler. Six months later he was seen by Dr. Owles who found him getting much weaker, apparently from over-exertion, though in walking and speaking he had improved, and there were no symptoms specially characteristic of "General Paralysis of the Insane." On some points his memory did not seem quite correct, but the confusion was not more than is general in those who had impaired their brains by the abuse of alcohol and other excesses. He was then for some time an out-patient at the National Hospital for the Paralysed and Epileptic, where he was under Dr. Ferrier, who reported that he found the symptoms to be those of general paralysis, very general tremulousness, defective articulation, and unequal pupils, but without any very well marked mental symptoms. The treatment was bichloride of mercury with perchloride of iron. The patient then went to St. George's Hospital, where basic pneumonia first showed itself, and in three days he died. The doctors at that hospital reported that they saw no symptoms of aphasia or signs of paralysis. No *post mortem* was allowed, but Dr. Owles thought the following conclusions probable:—

1. It was not a case of general paralysis of the insane. There was an absence of the most prominent characteristics of that disease, and the progress of the case would negative it.
2. If it was a case of aphasia, the aphasic symptoms, as Dr. Forbes Winslow expected, had almost disappeared in six months.
3. Though there was no proof of syphilis, there was evidence of alcoholism, and it seemed likely that this was the predisposing cause, both of the symptoms of paralysis and of the double pneumonia, from which he died.

Dr. THUDICHUM considered that, except in cases with syphilitic history, the use of mercury was disadvantageous, owing to its tendency to accumulate in the tissues.

Dr. DREWITT admitted he had great doubts as to the exact diagnosis when he first saw the case, still he did not think it necessary to have distinct mental symptoms, as that depended greatly on the situation of the disease.

Dr. BENNETT spoke of a case of alcoholism, the symptoms of which simulated those of general paralysis of the insane, and which got well under treatment.

Dr. OWLES then replied.

LIVERPOOL MEDICAL INSTITUTION.

THURSDAY, FEBRUARY 28TH, 1884.

The Effects of the Present System of Education upon the Health of the Community.

DR. HOWIE, who opened an interesting discussion on this subject, maintained, in an introductory paper, that no sustained and severe physical or mental work should be performed under twenty years of age. Hard work of any kind before twenty years of age shortened materially the time during which such work could be carried on. With children under twelve years of age, sleep should occupy twelve hours out of the twenty-four; meals, &c., four hours; physical exercise, four; and mental work, four. When he (Dr. Howie) entered College, he consulted Prof. Blackie as to the daily number of hours it was necessary to give to study. Two only were recommended; but Dr. Howie gave six, with the result that afterwards he was not able to open a book for years. He charged the School Board with cramming the children instead of educating them; with overloading the memory instead of training the reason; with trying to force into the minds of young children knowledge that could not be understood until they were older; and with thus causing that mental worry which more than anything irritated and weakened brain-tissue. It was said that 90 per cent. passed the examinations, but that only showed the amount of pressure that must have been brought to bear upon them. It was said that no visible signs of ill-health were to be seen amongst the children in the schools; but this was said by those who only "looked in" and saw the excited and curious faces of the children intent upon the visitor. It was said that very few break down, but medical men would say otherwise. He attributed two cases of tubercular meningitis to the worry of school life, and gave several examples where rapid improvement in health resulted from the giving up of study by children who were fond of school. After referring to the rapid increase of diseases of the nervous system within the last 30 years, Dr. Howie recommended—(1) the abolition of payment by results; (2) the improvement of the teachers, and the giving to them of larger discretionary powers; (3) the extension of the hours of play to three half hours daily, under supervision and in suitable playgrounds; (4) the entire exclusion of arithmetic from the standards. Quality, not quantity, ought to be the principle of education.

Dr. RAWDON was convinced, from his experience at the Children's Infirmary, that headache, depression and anæmia were on the increase amongst children, and were directly attributable to over-work in schools. Under twelve years of age, home lessons ought to be abolished. Some teachers said the children got on better without home lessons. He instanced two schools, one at the top of a hill where no home lessons were required to be learned, and another in a valley where home lessons were given, and the former far outstripped the latter in its results.

Dr. WILLIAMS showed how unfavourable were the homes of many School-Board children for the preparation of home lessons, these gutter children were, moreover, insufficiently fed, and although they had an apparent smartness, they were not nearly as intelligent as better fed and better cared-for children.

Dr. ALEXANDER would not ascribe the increase of nervous disease, such as epilepsy, to over-work in schools. In his experience the increase was due to hereditary transmission from their parents, whom he often found to be (one or the other) but one degree removed from the position of their afflicted children. Over-work, however, aggravated the growing tendency to these diseases. He gave an instance where the health of a School-Board child broke down (whether from over-work or from other causes he could not say); rest was absolutely needful, but it was near an examination when prizes and promotion were within reach of the child, when some relief from the expense of education was possible for the parent, and emoluments were in store for the teacher should the scholar pass the examination. In spite of remonstrance the child continued to work until it could not get out of bed, and was now probably "lamed for life." In this way the School-Board system had become an educational Juggernaut, that crushed the feeble or fainting, and so pressed on the strong that even they with difficulty escaped. The examining inspectors were often very injudicious and pressed the little ones with questions so framed as not to be easily understood. Gutter children had a special smartness, but it was smartness that often led to prison than to other forms of prominence.

Dr. ARCHER described the effects of badly constructed school-rooms on the production of myopia, and quoted the statistics of Greenwich Naval Hospital, where five and a half per cent. became myopic during three years sojourn in that school. Female pupil-teachers were especially hard pressed, and at a period of life particularly unfavourable for hard work.

Dr. HOPE considered that those educated at Eton and Harrow were much harder pressed than School-Board children. When the latter could not pass the standards, the teachers got the results just the same.

Mr. DANVER HARRISON cited a case of epilepsy under his care, where brain work brought on the attacks. During rest and a sea-voyage they completely ceased.

Dr. H. GREVES had been studying the causation of chorea, and he was convinced that hard school work, and especially the fear that the pupils entertained of the consequences of getting behind, were causes of that disease. He always prohibited lessons in such cases.

Dr. CATON thought the present system of education was a great advance upon the old state of things; but when Englishmen took up anything they generally went wrong at first. In Scotland, where there had been a general system of education for centuries, the physique was still good, and disease less prevalent than formerly. In Germany a very stringent system of education was in force, and yet he had not heard of the evils described by previous speakers. That nation instead had men prominent in every scientific and literary pursuit. In some schools the children lived in a constant state of fear, and their minds were consequently confused. The system of pupil-teachers was a great defect of the School-Board system. These teachers were very much over-worked, resulting in headaches and irritability, which peculiarly interfered with their usefulness as teachers.

Mr. EDGAR A. BROWNE thought the evidence to be brought forward by the medical men must be such as to convince the public and the teachers. The latter, like all literary men, demanded an increase in the death-rate before they could be convinced. They were not observant, and could not see the bad effects of cramming that were so apparent to every unprejudiced scientific observer. The evil tendency of forcing facts into children during a whole year, and then allowing an intellectual vomit, was so plain that we had not to wait for mortality statistics to prove it. Sun-light, fresh air, and exercise were the three things necessary to promote the growth of the children. At the present time these were only obtained in summer or on holidays. A school girl, the subject of myopia, consulted him a few days ago. Her daily work was as follows:—Rise at 7 o'clock; study 7.30–8 o'clock. Breakfast. Study from 9 to 1 o'clock. At 1.20 dinner. Study from 2 to 3.45. Tea, and "practice" till 6.30 o'clock. Study from 6.30 to 8.30. Prayers, bed at 9 o'clock. The only walk was to church every Sunday; and this was at a fashionable school. After a struggle with the mother he obtained a three months' holiday for the child. He recommended the Greek system of education, where a half-holiday was given every day, and was used in the pursuit of physical exercise.

A committee was appointed, consisting of Drs. Caton, Carter, Davidson, Gee, Greves, Howie and Rawdon, and Messrs. Browne, Hulke, and Paul, to investigate the subject and report upon it to a future meeting.

OBITUARY.

CHARLES GREIG, F.R.C.S. Edin.

THE subject of this memoir was born in Kent in 1816. His medical studies were pursued partly at the Bristol Royal Infirmary, and partly at St. George's Hospital. Shortly after obtaining his diploma he became house surgeon to the Bristol Royal Infirmary, a post which he held and filled in a most exemplary manner for six years. He then settled down in Clifton, and soon had a large and high-class practice there and in Bristol. Failing to obtain a vacant surgeoncy at the Infirmary, he did not offer himself for it again, but all through his career he devoted a considerable portion of his time to giving gratuitous advice to the poor. Of a benevolent and charitable disposition, but careful to avoid all ostentation, Mr. Greig has left a large circle of friends to mourn his loss. He had been out of health for a year, but it was only since Christmas that his illness had been thought to be serious. He died on February 27th.

GENERAL CORRESPONDENCE.

TONSILLITIS AND TONSILLOTOMY.

[To the Editor of the Medical Times.]

SIR,—I have been much interested and instructed by the "Clinical Papers" lately appearing in your journal, but I trust you will allow me to express my dissent from the latest contribution on "Chronic Tonsillitis and Tonsillotomy."

I will not trespass on your space by dealing categorically with all the points raised in the article, but shall merely touch on what seem to me the more important errors of the writer. "B." is evidently possessed with the idea that tonsils grow "again and again," after removal. I can only say that this view, which is stated three times in the short space of two columns, is entirely opposed to my own experience. Among the many hundreds of cases in which I have operated, I know of only two in which there was any sign of subsequent enlargement. As we are generally reminded of *un*successful cases, I am sure that if any considerable proportion of my operations had not turned out well, I should have heard at least of some of them.

In one of the two instances to which I have alluded, I believe that I performed the operation incompletely, or perhaps I should say insufficiently, whilst in the other a severe attack of inflammation (occurring long after the tonsils had been removed) left a little enlargement behind it. I have, however, seen many children a few weeks after they had been operated on by surgeons of the highest position, but whose experience on this particular point had been comparatively limited, in whom it was obvious that not nearly enough of the gland had been taken away. In these cases the patients' parents have usually told me that "the tonsils had grown again." I have also occasionally seen my pupils excise tonsils in such a way that it would be easy for any one afterwards to think that the "tendency to hypertrophy" had manifested itself anew. I venture to think that if tonsils were really endowed with the hydra-

like property which "B." attributes to them, I could not have failed to have met with some examples of it. My experience, however, is entirely favourable to tonsillotomy. The great benefit received by one child of a family has over and over again induced the parents to bring their other children to be operated on, as they have successively been attacked. Space will not permit me to detail the enormous permanent benefit I have seen following the operation, nor the prejudicial and even fatal results which I have known ensue from the enlarged glands being allowed to remain in the throat.

"B." seems to think that tonsillotomy is often performed on account of "chronic and fluctuating enlargement," a condition which he considers as diathetic and, therefore, unsuitable for operation. I will not here go into the question of diathesis, but if repeated attacks of painful inflammation can be prevented by a single operation, there appears to me to be the strongest reason for its performance. The writer of the article is under the impression that "in a very large proportion of cases" of enlarged tonsils, neither respiration nor deglutition is at all interfered with, and there is merely some unimportant tumefaction of the glands. That is to say, in a very large proportion of cases of enlarged tonsils, the swelling is slight, and no operation is called for. This may be quite true, but it does not touch the question of the usefulness of tonsillotomy where the hypertrophy is considerable. Of course if "B." can prove that the operation is generally performed in unsuitable cases, he has a strong position; but it appears to me strange that a single practitioner should have sufficient grounds for making such a statement. The rule which I have always laid down for the guidance of my class in the treatment of persons under twenty years of age is, that the operation should only be done when either the tonsils are *considerably hypertrophied*, or their superficial structure is so diseased as to give rise to frequent attacks of tonsillitis. The expression "considerably hypertrophied," however, as I have always been careful to explain, has a purely relative meaning, as a comparatively slight enlargement in a small pharynx may occasion more inconvenience than a much greater amount of hypertrophy in a large throat. In these cases the safest test is whether the condition interferes with respiration.

My letter is already longer than I could wish, or I should say a few words on the various methods of removing the tonsils. Perhaps on some future occasion you may be willing to allow me to discuss in your columns the relative advantages of tonsillotomy with the guillotine and with the bistoury.

I am Sir, &c.,

MORELL MACKENZIE.

Harley Street, W.
March 11th.

[The experience of a "single practitioner" may appear somewhat valueless when opposed to that of a leading specialist, even though it be gathered from the numerically large practice among out-patients at a special and also at a general hospital. Such as it is, however, it shows only too clearly that there are but few such skilful tonsillotomists as Dr. Mackenzie, since partial removal is the rule and not the exception. Personal experience alone has amply sufficed to show that re-growth takes place often with troublesome rapidity, even after somewhat free removal. Without doubt, "if repeated attacks of painful inflammation can be prevented by a single operation," such an operation should not be delayed. To prove, however, that Dr. Mackenzie's teaching upon this point has not spread so widely in the profession as he might desire, it is sufficient to point to the vast number of children who are allowed to go about with large tonsils, exposed to such attacks as he refers to.—B.]

THE EDINBURGH TERCENTENARY.—M. Caro, for the French Academy, and MM. Pasteur and d'Abadie, for the Academy of Sciences, will attend as delegates the *fêtes* at Edinburgh in commemoration of the tercentenary of the foundation of the University of Edinburgh.

CHOLERA.

[To the Editor of the Medical Times.]

SIR,—May I ask you to be so obliging as to publish the following remarks, which I cut out of my observations for the Epidemiological Society, in order to shorten them and also because it was introducing fresh matter, in the discussion of Sir W. G. Hunter's paper, to which, as a visitor, I felt I was not entitled.

"There seems no reason why cholera should not be the outcome of over-crowding, defective ventilation, over-feeding and heat in a low-lying district, any more than that similar conditions should give rise to typhus, plague, and perhaps cerebro-spinal fever, while defective ventilation, filth, and over-crowding are the main causes of typhus and plague; it is known that cholera does not invade famine-stricken districts, nor spread in sandy deserts, yet it does break out among well-fed coolies, and even soldiery, where there is in addition over-crowding and idleness and, let me add, for all these diseases—mental depression from discontent.

"I am not aware that typhus fever has a specific entity,[1] yet it is infectious; nor that a specific germ has been discovered for cholera, yet within certain limits the dejecta are poisonous. Typhus poison mixed with cutaneous and lung matters is readily decomposed, oxidised, and rendered inert. Cholera poison united with intestinal out-pourings is not so rapidly oxidised as the former, owing to the medium through which it is oxidised. This, like typhus, is also carried by fomites.

"An intelligent and practical engineer informed me, he had often been struck with the immunity from disease of men working in sewers, while those on sewer banks often succumbed to disease. The explanation, I venture to think, will be found in the condition of maturity or oxidation in which the poison is presented to the recipient, just as the fatal after-damp in mines, exuded under pressure, presents a trickling stream, which on expansion becomes the fatal gas.

"I cannot think that a case of sporadic cholera would breed in a temperate climate, but that in a warm one it might readily do so under fostering conditions. When such a case occurs the doctor has to consider whether he has to treat a case of poisoning, summer diarrhœa, perforation of bowel, enteritis, or ague. The first three are easily disposed of. Enteritis is common in warm climates. Such a case occurred to me on February 24th, 1872. It was only on the *post-mortem* table that general enteritis—probably from a tænia found—accounted for the symptoms possessing every feature of cholera. The season of the year and absence of any epidemic unhealthiness enabled me to decide against its infectious character, and to allow the poor patient the nursing of his wife in a separate ward.

"I think the evacuations of such a patient, passed into a drinking supply, are capable of initiating similar symptoms in warm climates, and if meteorological conditions favour endemic and epidemic cholera. Some people cannot live on certain soils without contracting illness. Disease also thrives better on some soils than others. Hence poisonous germs introduced into a country may thrive, or find soil-antagonism and die."

Cholera may begin as ague, and I confess to the difficulty of diagnosis in the first cases of an epidemic.

I remain, Sir,

Yours truly,

Preston,
March 10th, 1884.

CHARLES MOORE JESSOP.

[1] Unless the micro-organisms described by Mr. F. W. Mott and Mr. J. Blore, in *British Medical Journal* of 1st December, 1883, are to be regarded as such.

THE LATE MR. WHEATLEY.—A subscription has been set on foot among the Fellows of the Royal Medical and Chirurgical and other Societies which Mr. Wheatley served in the capacity of Librarian, to increase the slender provision he was able to leave for his sister and niece.

NEW INVENTIONS & IMPROVEMENTS.

THE SHELFANGER TONIC TABLE WATER.

It is gratifying to notice the gradual development of the English mineral waters, to keep pace with the growing demand of the present day. There can be no doubt that they might, before long, if sufficiently made known, fairly distance, in the race of competition, many of the imported, and hence more costly, articles of the same nature. In the Shelfanger Natural Mineral Water, discovered not long ago by a member of the medical profession near Diss, in Norfolk, and now steadily advancing in public estimation, we have a mild alkaline chalybeate water, in which the iron existing (in proportion of three grains to one gallon) in the form of carbonate is combined with such an amount of alkaline and magnesian salts, that its astringent qualities are fairly balanced and neutralised, while its tonic and recuperative powers remain in full exercise. When we add that the Shelfanger water is singularly pure, sparkling, and most palatable and refreshing, and that it is discharged, fresh from the spring, at the rate of 650 gallons per 24 hours, we may easily understand its increasing hold on the market—at the very reasonable price at which it is offered.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.

At the ordinary meeting of the Council on Thursday last, the 13th instant, the chief business consisted in authorising the President to apply to the General Medical Council for the sanction of that Council to the scheme for constituting an Examining Board in England, under the provisions of Clause 19, of the Medical Act, 1858, agreed upon by the two Colleges, in the early part of last year, such sanction to be effective only on the Medical Acts Amendment Bill, now before Parliament, *not* becoming law. Mr. Flower's resignation of the office of Curator of the Hunterian Museum was next considered; it was accepted with expressions of sincere regret, and high appreciation of his valuable services to the College during the 22 years he had held office. The question of appointing his successor was referred to the Museum Committee to consider and report upon.

At the Meeting of Fellows and Members of the Royal College of Surgeons, which will be held on 24th of March, 1884, the following alterations in the Charters of the College, adopted by the Council on the 10th of January, 1884, will be reported :—

1. That the Section of the Charter of George IV., which restricts the amount of property in lands or rents to be held by the College to 2,000*l.* be altered so as to provide that such amount be increased to 10,000*l.*

2. That Section 5 of the Charter of the 7th Victoria be altered so as to provide that the conditions of admission to the Fellowship by examination and the arrangements for the examinations for the same, be in future determined by resolutions of the Council, and not by by-laws as required by such section.

3. That in Section 7 of the Charter of the 7th Victoria, the amount of the fee payable for the Fellowship by examination be omitted, leaving such amount to be provided for by by-law.

4. That Sections 15 and 16 of the Charter of the 7th Victoria be altered so as to provide that the mode of election to the Council may be by voting-papers as well as in person, the quorum of Fellows required to be present at the meeting for election being omitted from such sections, it being desirable that, in future, such quorum be determined by by-law instead of by Charter.

5. That in Section 5 of the Charter of the 15th Victoria the words beginning "and the fee," &c., to the end of the section be struck out, it being undesirable that any fee should be paid by Members of twenty years' standing on election to the Fellowship.

6. That Section 17 of the Charter of the 15th Victoria be abrogated, it being inexpedient to continue the examinations for the licence in midwifery of the College.

7. And that Sections 1 and 2 of the Charter of the 23rd Victoria be altered so as to provide that the number of members of the Board of Examiners in Dental Surgery may, if thought desirable by the Council, be increased beyond six, the present number, and that the section of the Board consisting of persons skilled in dental surgery be restricted to dental practitioners duly registered under the Dentists' Act of 1878.

We would especially remind gentlemen who may wish to propose any amendments or alterations that they must hand in such amendments *in writing*, with the names of the proposer and seconder in due form. This is not intended to stifle discussion or to prevent suggestions being made, but rather to secure a formal and business-like consideration of them.

MEDICAL SICKNESS ANNUITY AND LIFE ASSURANCE SOCIETY.

Meeting of the Provisional Executive Committee.

A meeting of the Provisional Executive Committee of this Society was held at 38, Wimpole-street, W., on Thursday, March 6th. The following members were present:—Mr. Sibley, Surgeon-Major Evatt (Woolwich), Dr. Clibborn, Mr. Brindley James, Mr. Major Greenwood, jun., Mr. Radley (Secretary), Mr. E. Noble Smith (in the Chair). The minutes of the last meeting were read and passed. The Secretary reported that letters had been received from Mr. J. Bain Sincock (Bridgwater), and Mr. Behrendt (Birmingham), stating their inability to attend. The Secretary presented his report showing that 300 members had joined, and that the receipts amounted to 185*l.* 7*s.* 2*d.* The report was received and adopted. The Chairman stated that a letter had been received from Mr. Ernest Hart, expressing his satisfaction at the progress of the Society, and making suggestions with regard to its further extension, which were unanimously approved. The Secretary recommended, that as it had been decided after consultation with their consulting actuary, Mr. Neison, to accept members for sick-pay only, who were unwilling to join for sick-pay and annuity combined, the two funds be kept distinct, and that separate tables be drawn and printed, showing the rates for sick-pay only. This was duly proposed and carried. A letter was read from Mr. Parsons (Ambleside), asking whether gentlemen retiring from practice, after becoming members of the society, were open to receive the benefits of the society? An answer was directed to be sent in the affirmative. A communication was read from a correspondent, who desired to know if members of the Army and Navy Medical Services, liable to be called out of the country on duty, would be eligible as members of the society. It was decided to reply that the society was at present too young to undertake the risks this would involve. The question of holding a general meeting in London was discussed, and its further consideration was deferred. A discussion, arising out of questions connected with the proposal forms referred to the meeting, brought the proceedings to a close.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 6, 1884 :—

Cusse, Ernest, Great Ormond Street, W.C.
Humphreys, Fras. Rowland, Queen Street, Finsbury, E.C.
Kebbell, Charles, Brunswick Place, Brighton.
Nance, Arthur Stanley, of the Metropolitan Free Hospital, E.

The following gentleman also, on the same day, passed the Primary Professional Examination :—

Stericker, Geo. Frederick, of the Leeds School of Medicine.

King's College Hospital.—At the annual court held on the 28th ultimo, the Secretary read the 45th annual report, which stated that during the year 2,094 in-patients had been admitted, and 21,403 persons had been treated in the out-patient department, besides 6,183 casualties which had been attended to in the surgery of the hospital, and 657 poor married women attended in their confinement. The expenditure of the hospital during the year had amounted to 15 448*l.* 11*s.* 2*d.* The total income of the year, including the proceeds of a very successful festival dinner, amounted to 12,609*l.* 2*s.* 4*d.*, leaving a deficit of 2,859*l.* 8*s.* to be paid out of capital. The legacies which, for the ten years ending 31st December, 1880, averaged nearly 6,000*l.* a-year, amounted during the past year to only 1,377*l.* Referring to the medical school of King's College, the report acknowledged the excellent work done in the hospital wards by the physicians and surgeons forming the entire staff. The committee also recorded their gratitude to the medical officers of every grade for the great services which they had rendered to the hospital, and to the sisters and nurses employed by St. John's House, for their sedulous care of the patients under their charge. The report was unanimously approved.

National Health Society.—The eleventh annual report of the National Health Society, 44, Berners-street, W., shows that the Society has carried on its work during the past year in a most practical manner. Hundreds of lectures on sanitary subjects have been delivered, not only all over the poorer parts of London, but in provincial towns, to large audiences of working men and women, classes of girls, district visitors, and others engaged in work amongst the poor. The Society is much encouraged by the practical results of the lectures on keeping the house healthy; rearing of infants; prevention of the spread of infectious diseases; preparation of food and kindred subjects, knowledge of which is so much needed in our crowded neighbourhoods. The question of poisonous dyes in domestic fabrics; of smoke abatement; of dust collection and the prevention of cholera, have been investigated and reported upon by special committees appointed for the purpose. The Health Exhibition held by the Society last June was commented upon, and the Secretary stated that more than 100 members had joined the Society during the past year.

Physical Education of Girls.—A most interesting demonstration of gymnastics for girls—by the pupils of Miss Chreiman's classes—was given on the 5th inst., at the Town Hall, Kensington, under the auspices of the National Health Society. Lord Brabazon was in the chair, and a very large assemblage of members of the society and their friends were present. Dumb-bell exercises, gymnastic dances, and vocal marches were gone through with great precision and grace by the young athletes. Mr. F. Treves spoke on the importance of such training for growing girls, and Lord Brabazon expressed a wish that it could be extended to School Board children. Dr. Farquharson, M.P., W. Woodall, Esq., M.P., Mr. Noble Smith, and Mr. James Heywood also addressed the meeting; and several letters were read, expressing sympathy with the endeavour to physically educate and develop our growing girls—the future wives and mothers of England.

The St. John Ambulance Association.—The presentation of certificates to the successful students attending the classes of this association, took place recently in Exeter Hall (the Lower Hall). Mr. V. Barrington Kennett, who occupied the chair, said the certificates to be given that evening were to the students of the Young Men's Christian Association connected with Districts Nos. 2 and 3. The prospects of the association were never brighter. Not only were there now 120 districts in England, but there were also classes in India and Australia, and our cousins in America had also formed classes, though they were not connected with the association. They had three distinct classes of work, namely, classes such as the students present had attended, the distribution of ambulances and litters to stations in various places, in crowded towns and in factories, and an admirable system for transporting injured persons to hospitals. There was scarcely a police-station in London in which there was not an ambulance ready to convey an injured person to an hospital, and a policeman who had received the certificate of the association. The instruction had been given on a large scale, 8,000 certificates having been issued last year, making a total of 60,000 which had been issued since the formation of the association. The annual meeting of the Dublin Centre of the St. John's Ambulance Association was held in the Senate Hall, of the Royal University, on Saturday, March 8th. Mr. Francis Robert Davies, Kt., S.J.J., occupied the chair. The report stated that some of the branches of the Dublin Centre had been very active during the past year. During the year full courses of instruction were attended by 617 persons; certificates were obtained by 323, of which 227 were first aid, and 96 nursing. A large number of the metropolitan police had been instructed, and amongst those who received certificates, were one inspector, two sergeants, and 46 constables.

Royal Sea Bathing Infirmary.—An influential meeting was held at the Mansion House on Monday, in support of a special appeal in aid of the Royal Sea Bathing Infirmary at Margate. The Lord Mayor, M.P., presided. The institution now had accommodation for 220 in-patients, and being open all the year round, it received annually from 600 to 700 patients from London and all parts of England. The benevolence of Sir Erasmus Wilson had provided the Infirmary with a new wing of four wards, a swimming-bath, and a chapel, and the drainage and sanitary arrangements were in perfect order. The outlays on the new buildings, and in the enlargement of the old, had diminished the funded property of the charity by between 6,000*l.* and 7,000*l.* The increased annual expenses would require an addition to the income of 2,000*l.* a year. The ordinary expenditure was 8,669*l.* annually, and the ordinary income was but 4,423*l.*, leaving a large deficiency to be supplied by exceptional benevolence.

National Eye and Ear Infirmary, Dublin.—The annual meeting of the directors of this body was held at their rooms, Molesworth Street, on Thursday, March 6th. Mr. Swanzy read the report, which showed that 348 patients were admitted during the year, as compared with 325 in 1882; while the number of days spent in hospital was 8,021, as compared with 6,319 in the previous year. In the Dispensary for Diseases of the Throat, which was established two years ago as an adjunct to the Ear Department, 94 patients have been treated during the year, and of these a large proportion consisted of aural patients, who were found to have throat complications. The total number of visits paid by these patients was 330, with an average daily attendance of 3·2. The balance-sheet showed the subscriptions and donations during the year were 307*l.* 17*s.*; grant from the Hospital Sunday Fund, 91*l.* 4*s.* 5*d.*; from the Corporation, 100*l.*; received from patients, intern, 250*l.* 18*s.* 3*d.*; extern, 97*l.* The treasurer's account stated that the balance in bank at close of year was 21*l.* 2*s.* 11*d.*, but the unpaid accounts exceeded 91*l.* 10*s.*, and the institution was over 70*l.* in debt.

The Dental Hospital of London.—The 26th Annual Meeting of this Institution was held on the 13th inst., under the presidency of Mr. Erichsen. In the report, which was unanimously adopted, the managing committee congratulated the Governors on the continued prosperity of the Institution; 35,622 cases had been treated during the year 1883, a large number of them painlessly (under anæsthetics). Sir Edwin Saunders had made a munificent gift to the charity of the lease for over 90 years of the "Tower House," adjoining the Hospital, valued at 2,400*l.*, for the purpose of its enlargement. A special appeal had been issued for the funds necessary for fitting up and adapting the new wing, and for redeeming the mortgage debt of 5,000*l.* on the hospital building, and the managing committee gratefully acknowledged 1,132*l.* 4*s.* in response.

Volunteer Ambulance Department.—It is announced from the War Office, that volunteers who have gone through a course of instruction in stretcher-drill, and field-dressing, and have passed a satisfactory examination therein, will receive from the Volunteer Ambulance Department a certificate. Two volunteers from each company who have so qualified will be selected by the commanding officer of the corps, on the recommendation of the medical officer, to

the stretcher-bearers of the corps, and to wear the Geneva badge on the right arm, and they will be entitled to wear the badge from year to year, on certificates by the medical officer of the corps, that they have attended not less than four ambulance drills during each year, ending October 31st.

THE PARKES MUSEUM.—Among the members elected at the last meeting of the Council of the Parkes Museum were :—Sir William Bowman, Bart., F.R.S.; the Hon. Sir John Rose, Bart., G.C.M.G.; Sir Henry B. Loch, K.C.B.; Sir Frederic Abel, C.B.; Mr. J. Bonham Carter; Surgeon-General James Monat, V.C., C.B.; Professor H. E. Armstrong, F.R.S.; Major H. B. Hamilton; Dr. S. O. Habershon, F.R.C.P.; Mr. W. Emerson, F.R.I.B.A.; Mr. J. Cooper Forster, F.R.C.S.; Stephen Salter, F.R.I.B.A.; Dr. John Williams, F.R.C.P.; Mr. Morrant Baker, F.R.C.S., and Mr. Thomas Bryant, F.R.C.S.

BRITISH HOME FOR INCURABLES.—The Right Hon. the Lord Mayor has consented to take the chair at the Festival at the "Freemasons' Tavern," on the 18th instant, in aid of the funds of this excellent institution, when the Board of Management hope sufficient subscriptions will be raised for a "Lord Mayor Fowler's Board," or "Pension Fund."

APPOINTMENTS.

APPLETON, THOS. A., M.R.C.S., L.S.A.—Medical Officer to the Second District, Fulham Union.

BUCHAN, W. A., M.B.—House Surgeon to the South Devon Hospital, Plymouth.

DARBISHIRE, S. D.—Clinical Lecturer at the Radcliffe Infirmary, *vice* Dr. Gray, resigned.

DOWNIE, J. W., M.B.—Lecturer on Diseases of the Ear and Throat, at the Western Medical School, Glasgow.

OLIPHANT, E. H. LAWRENCE, M.B., C.M. Ed.—House Surgeon to the Glasgow Maternity Hospital.

MCCLELLAND, J., M.D., M.R.C.S.—Honorary Physician to the Liverpool Infirmary for Children, *vice* Dr. Armstrong, resigned.

NANCE, H. CHESTER, M.R.C.S., L.R.C.P. Lond., L.S.A. — Senior Resident Medical Officer to the Hospital for Sick Children, Pendlebury, Manchester.

POWELL, S., M.B., M.R.C.S.—Assistant Physician to the Hospital for Epilepsy and Paralysis and other diseases of the Nervous System, Portland Terrace, Regent's Park.

RICHARDSON, HENRY E., L.R.C.P., L.R.C.S.—Senior House Surgeon to the Borough Hospital, Birkenhead, *vice* M. Bernstein, resigned.

SMITH, FREDK. M. G., L.R.C.P. Edin., M.R.C.S. Eng.—Medical Officer to the Droxford District and the Workhouse, Droxford Union.

VINCENT, HENRY B., M.R.C.S. Eng., L.S.A.—Medical Officer to the Workhouse, Mitford and Launditch Union.

WOOD, G. B., M.B., C.M.—Resident Medical Officer to the Jersey General Dispensary.

VACANCIES.

BRIDGNORTH INFIRMARY.—House Surgeon and Secretary. Salary £130 per annum, rising £10 per annum, to £150, with rooms, coal, gas, and attendance. Candidates must possess registered Medical and Surgical qualifications. Applications, with testimonials, to be in the hands of the Secretary by the morning of March 18th.

ESSEX AND COLCHESTER GENERAL HOSPITAL, COLCHESTER.—Physician. Candidates must be graduates in Medicine of one of the Universities recognised by the Medical Council of the United Kingdom, or Fellows or Members of the Royal College of Physicians of London, or Fellows or Licentiates of the King and Queen's College of Physicians of Ireland, or Fellows of the Royal College of Physicians Edinburgh, but no candidate shall be eligible who practises, or is connected in partnership with any one who practises Surgery, Pharmacy, or Midwifery. Applications, with diplomas and testimonials to be sent to the Secretary, on or before March 19th.

They must attend, if practicable, at the meeting of the Medical Council, on Tuesday, 1st April, at 3·30 o'clock p.m. Applications and testimonials, to be sent to the Secretary, on or before March 31st. Applications are also invited, in the event of an Assistant Surgeon being elected, for an Assistant Surgeon.

WOODBRIDGE UNION.—Medical Officer to First and Second Districts, in succession to Dr. E. F. S. Green, resigned. Area 19,577 acres. Population 2,917. Salary £80 per annum.

WOLSTANTON AND BURSLEM UNION.—Medical Officer to Kidsgrove District, in succession to Mr. A. W. Strickland, resigned. Area 3,171 acres. Population 11,365. Salary £35 per annum.

DEATHS.

HOGG, HENRY LEE, M.R.C.S., L.S.A., at Cleobury Mortimer, Shropshire, on March 3, in his 71st year.

SHARMAN, MALIN, M.R.C.S., at Hollington, Bristol-road, Birmingham, on March 10, aged 59.

WALKER, HENRY, M.D., J.P., at Brierley Hall, on March 6, in his 65th year.

WATSON, THOMAS SANDEN, M.D., at 9, Lansdown-crescent, Bath, on March 6, in his 84th year.

NOTES, QUERIES, AND REPLIES.

THE HIND FUND.

The following additional subscriptions have been received and paid to the account of the "Hind Fund" at Messrs. Coutts' Bank:—Sir Andrew Clark, Bart., £5 5s.; Sir Prescott Hewett, Bart., £5 5s.; Dr. J. C. Graham, Sumatra, £5; Robert Evans, Esq., £3 3s.; F. Manton, Esq., £2 2s.; Dr. Alex. Marsden, £2 2s.; Dr. Lloyd Roberts, £2 2s.; P. B. Giles, Esq., £1 1s.; J. R. J., £1 1s.; Geo. D. Pollock, Esq., £1 1s.; T. L. Leak, Esq., 10s.

Subscriptions may be paid to Dr. Richardson, F.R.S. (chairman), 25, Manchester-square; John Tweedy, Esq., F.R.C.S., 24, Harley-street, hon. treasurer; A. J. Pepper, Esq., F.R.C.S., 122, Gower-street; and T. Wakley, jun., Esq., L.R.C.P., 95, Radcliffe-gardens, hon. secretaries; or to Messrs. Coutts and Co, Strand.

A SUGGESTION.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—In reading the lectures of Drs. Matthews Duncan and S. Wilks, on "Amenorrhœa and Vicarious Menstruation," in the *Medical Times* of February 2nd and 9th respectively, my thoughts turned to diaphoretics, diuretics, &c., and I wondered if it were not practicable and sensible to apply the same ideas these gentlemen have set forth in respect of vicarious menstruation and emmenagogues, to substances having properties which have been assigned them from time immemorial, and which are intended to do in another sphere what emmenagogues have been supposed to do for amenorrhœa.

I am, Sir, &c.,
GEO. H. CLARK,

W. Walnut Lane,
Germantown, Philadelphia, U.S.A.
February 26th, 1884.

An Unusual Cause of Bankruptcy.—At the Dudley County Court, on March 11th, inst., during the public examination of Mr. George Gilbert, bricklayer, it was stated that his failure was due to the payment of over £2,000 to different physicians and other medical agencies during the long illness of his wife. One item was £84 paid to a London physician for one visit to Birmingham. The bankrupt passed his examination.

COMMUNICATIONS RECEIVED—THE RIGHT HON. THE LORD MAYOR OF LONDON; Sir EDMUND LECHMERE, London; Prof. G. BUCHANAN, Glasgow; Dr J. HUGHLINGS JACKSON, London; Dr. T. CLIFFORD ALLBUTT, Leeds; Mr. C. BEING THE GULSTONIAN LECTURES DELIVERED AT THE ROYAL COLLEGE OF PHYSICIANS, LONDON,

By T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., F.R.S., F.R.C.P.,

Senior Physician to the Leeds General Infirmary.

LECTURE III.—[Abstract.]

DR. ALLBUTT commenced by remarking that enteralgia was, perhaps, the most racking torture contained in the curse of mankind; so bitter, so searching was the agony, that more than one sufferer had said to him, calmly regarding his by-gone pains, that surely the sting of death would have been more welcome. In the handbooks of medicine of late years, this malady had received but a scanty and indistinct recognition, it had been so often confounded with common gripes, on the one hand; or, contemptuously tossed over to the limbo of hysteria, on the other. He made an exception, however, in favour of the writer in "Reynold's System of Medicine."

The two chief points of onset were the umbilical region, and the right flank. The central attacks were not strictly umbilical, but arose at a point usually about two inches to the side, generally the right side, of that mark, and the lateral attacks were generally a little higher than the iliac fossa, being nearer the back of the crest of the ilium itself. Gastralgia, he had already pointed out, was commoner in women by two to one, but of fifteen marked cases of enteralgia, eight occurred in men and seven in women. The four most severe instances were all in men of ages between 22 and 48. Cases of mere tormina, consequent upon irritation of the bowels or constipation, and cases of lead poisoning had been excluded, not because they had no element of visceral neurosis in them, but because it was his object to study the malady in its purest form. The greater relative frequency of enteralgia in men than of gastralgia might be explained in part by its being more directly allied to gout than was gastralgia, and partly by its dependence on the weightier stress of the larger affairs of men.

A family history of gout was characteristic of enteralgics rather than of gastralgics. Enteralgia, like sciatica, might be a "pure neurosis," but was, like it, not rarely of gouty nature. Enteralgia was due rather to the strife of public life, than to the teasing of homely worries.

In illustration of his views the lecturer quoted a series of cases:—A clergyman who had suffered from attacks of pain in the right flank, stabbing pains, causing frightful agony, followed by serious collapse and prostration; the patient was somewhat neurotic, but not melancholic or hypochondriacal. In another instance, also that of a clergyman, the chief pain was just

to the right of the navel, and was described as going through the liver and round the right side to settle in the kidney; the patient had improved on arsenic, quinine, and belladonna. In another case, that of a medical man, the patient had an abiding pain in the right flank, aggravated by jolting, as in riding or driving over a rough road; there was no evidence of any local disease. In another case, that of a lady, there was a distinct tendency to periodicity in the attacks, which were liable to come on in the early part of the night; the attacks were apt to be induced by fatigue, or by exposure to cold. Vomiting was not usually present in cases of enteralgia, nor was constipation more common than in other atonic affections.

After alluding to other cases, Dr. Allbutt mentioned that of a lady who described her sensations during the attacks as if a corkscrew were being driven into her side; the onset of the pains in her was very sudden, causing her to stand still like a statue, alternately flushing and turning pale; she had a very neurotic family history, and was cured by arsenic, quinine, bromides and belladonna. After alluding to a case in which gouty phenomena, migraine and facial neuralgia had preceded enteralgia, Dr. Allbutt concluded this series of cases by referring to that of a young man, in whom enteralgia was preceded by epilepsy.

The next series of cases included those where the patients rightly, as he believed, referred the pain to the hepatic flexure of the colon; this pain he described as follows:—

"It is not severe nor periodic, it is rather wearisome and abiding. It is found in the melancholic rather than in the brisk neurotic, but, like enteralgia, is, I think, clearly associated with gout. Although not connected with obvious disorder of the bowels, yet a course of blue-pill and Carlsbad water generally relieves it—a course which would drive an enteralgic subject into a frenzy." The pain of lead colic, though probably of immediate nervous causation, was, nevertheless, not difficult to diagnose from the preceding forms. It was more diffused than enteralgia, and more extended than the pain of melancholia. It was periodic, doubtless, but it was rarely excruciating, rarely a slashing pain. It was rather of a grinding or fretful character. The parallel constipation and other circumstances would always serve to differentiate it in those few persons who, suffering from lead poisoning, had no blue line.

In regard to the neuralgias of other viscera, we were met, he said, by the difficulty, as yet insuperable, of proving definitely in what nerves the pain might lie. All essays to localise abdominal pains in the splanchnic nerves and their paths to the sensorium, in the sensory fibres around the large arteries, or in the deeper connections of the spinal nerves, were mere gymnastics, barren exercises, which might stimulate the fancy, but which as yet could neither be proved nor disproved. "We can only find our way," said Dr. Allbutt, "through those obscure gates and alleys of the body, by patient clinical watchings, by grouping and contrasting our cases, and by noting the curious warps of disease." Careful clinical observers, such as Anstie and Spender, said there were such disorders as hepatalgia and nephralgia, and he was disposed to agree with them. He had watched three cases in which neuralgia seemed to be seated in the liver. In one, the patient had pain referred to the seat and area of the liver, it attacked him only at night, he had had no jaundice, and did not suffer from constipation. He recovered under the use of bromides and arsenic. Dr. Spender and Dr. Anstie had given excellent descriptions of this affection, the latter noting, as characteristic, a peculiar mental depression which accompanied the pain. As a parallel case to one given by Anstie, Dr. Allbutt mentioned the case of a young lady, aged 22 years, who suffered from attacks of pain in the hepatic region passing to the stomach. The family history showed decided neurotic tendencies. Her complexion was clear, and there was no anæmia. He had subsequently learned that on two occasions she had passed a gallstone. In two other cases that he mentioned, a for some time unexplained hepatalgia was found to be associated with the existence of gallstones. He thought that these cases suggested hepatalgia. Was a sub-hepatic pain, arising in the gall bladder and ducts, due either to the irritation of gallstones, or some vicious quality of the bile? This was how he would explain cases in which pain of hepatic and epigastric origin recurred frequently and violently at times between attacks, which were obviously due to the travelling of gallstones on the move. "At present, then, I regard hepatalgia," he said, "as a pain aroused by the coincidence of an impressionable or neurotic habit, with the presence of gallstones at rest in the bladder. That pain may not arise in these tubes independently of such or similar irritations, I will not of course assert."

Passing on to consider the subject of nephralgia, he mentioned the following case:—A lady, aged 41 years, had one morning been seized with very intense pain in the loins, chiefly on the right side. The attack lasted three hours, the pain going round the right side of the abdomen, and down the groin into the thigh. Micturition was frequent for some hours. These pains recurred every morning at the same hour, though with less severity; no cause could be found for the attacks, but a little sandy matter was present in the urine. It seemed probable that this was a mixed case, both the kidney itself and the nervous system being at fault; but the nerve condition was probably playing the chief part, because the patient was a highly nervous woman, and had suffered from other forms of neuralgia, because there was a decided tendency to periodicity in the attacks, and because no other considerable cause could be discovered. The gritty matter, already alluded to, was probably the determining cause. In another patient the pain was situated in the region of the right kidney; it was continuous with exacerbations; it followed the course of the ureter, and caused cramps and collapse; the urine afforded negative evidence only, and the patient improved on quinine and belladonna. After alluding to another somewhat similar case, Dr. Allbutt said that in chronic renal disease, granular kidney especially, gastralgia was apt to appear. He then quoted some remarks of Dr. Ralfe's on two cases of renal neurosis in connection with aortic regurgitation, "renal storms," as they had been called by the late Dr. Murchison, and by Dr. Habershon in his Lettsomian lectures.

Pains in the other viscera he passed by without mention, as the remarks he had already made were applicable to them all; but neuralgia of the rectum he recognised as a definite, not very uncommon, malady—the pain was rarely of a very violent character. Neurotic diarrhœa was, he said, a tolerably well recognised troublesome affection; in it the stools, though slackened, were rarely watery, and did not contain much mucus. Pain was variable, and the attacks were reproduced by nervous causes; both sexes were equally liable to it, and it was generally associated with other neuroses, such as migraine, or cardio-vascular instabilities. It was found at all ages, and arsenic was positively harmful.

Passing on then to consider the genetic affinities of the class of patients to whom reference had been made in his remarks, Dr. Allbutt said that the first fact that struck him was the frequent association of neuroses of the vagus with certain kinds of eczema, lichen, and psoriasis. Their frequent occurrence in asthmatics was generally recognised; he believed that eczema and its allies were as common in gastralgics as in

asthmatics. The skin affections and the gastralgia, if concurrent in the family, might not be concurrent in the individual, or if they were, they might not be contemporary in him, nor parallel in severity. In illustration he mentioned the case of a patient who had been treated by him for neuralgia, and who came back saying that the medicine had also cured him of his eczema. Another case in point was also alluded to. Some one had called gastralgia, eczema of the stomach, an assumption with as little of probability as of proof. Was gout then to be regarded as the spring whence arose these skin affections, gastralgia and asthma? Not directly he thought, though he believed in some remote affinity between them.

The distinction between the eczema, lichen, and psoriasis of "dartrous" and those of "gouty" habits, was partly to be seen in the histories of the patients and of their relations, and partly, though not so readily, in the characters of the eruptions themselves. In the dartrous, these eruptions tended rather to be more acute, more symmetrical, to moisten, to spread, and to itch greatly, while in the gouty they tended rather to limitation, to dryness, to lack of symmetry, and to a less active tint of hyperæmia.

The dartrous diathesis of Bazin and others had gastralgia among its evolutions, as the gouty might have; but the term dartrous might well be put in a subordinate place, and the term neurotic diathesis used to indicate the family. Healthy persons with dartrous eruptions were often found to belong to neurotic families. Two brothers illustrated this. The one was a very healthy man, with the exception of a continual liability to eczema; the other was an asthmatic. There were other strong neurotic characters in the previous generation. "But lately," he went on to say, "an odd thing happened to me. A young man, seemingly very healthy, came to me for severe gastralgia of a pure type. I pressed him as to skin eruptions, but he denied their presence in himself and in his family. Within the next six months there came to my rooms, first, his sister, a healthy looking girl, with recent and vicious eczema around both ears; then the mother, with symmetrical moist, spreading eczema of the legs; and, finally, the baby of another daughter, with eczema of the head. These successive cases were almost put down to my ominous enquiries, and in an earlier time I might have been burnt. There was no gout in the family, nor any suspicion of its latent presence."

Another diathesis that had to be taken into account was the rheumatic. A young lady, in whose family antecedents rheumatism was a marked feature, suffered from neuralgia which was replaced by gastralgia, this was only cured by a liberal diet and the use of strychnia. Did such cases show any direct tie between the rheumatico-gouty diathesis, the eczema and the visceral neuroses? He did not think there was any such direct tie. But there was another affinity which had to be taken into consideration. In the history of many neurotic families phthisis was present, a fact common to all the neuroses, and not confined to the gastro-abdominal only. Cases in illustration of such association were quoted. The coincidence of phthisis and rheumatic fever in family trees had been noted by other observers as well as himself. "To my mind then," Dr. Allbutt proceeded, "the natural group is neurosis, phthisis, and acute rheumatism. But what of the gout? Rheumatism and gout are certainly akin, the two maladies appearing in the same families, and even in the same persons at different ages. Yet I think gout goes by a different route to its direct work. A pure neurosis goes hand-in-hand with phthisis and acute rheumatism; but pains which, like migraine, enteralgia, sciatica, and so forth, may in such association be of the pure type, may in other instances be caused by the poison of gout, and thus should be put into a separate class, with the eczema and psoriasis of gout, which again are not 'dartrous.'"

In the one class, the neuralgias depended upon some congenital defect of nutrition, affecting the nervous apparatus itself; in the other class, the nervous apparatus originally healthy enough, or even vigorous, was angered by a circulating poison. Yet was there not some alliance beyond this, was there not some remoter pathological kinship, unexplained by the humoral theory? He believed there was, and that farther back there was some community of nature between the gouty and the neurotic habit; and to this we might ascend when we tracked out those phenomena which suggested that gout was itself originally a neurosis. Although there was then no cross alliance between neurosis, phthisis, and gout, yet we could trace the history of gout upwards to a point of union with a divergent stock which, two, three, or four generations back, had branched off into the tuberculo-neurotic.

In this form anti-gouty remedies were of no avail, nor did they succeed in those cases where neuralgias or skin affections, set up in the first instance by gout, had been left behind after the causing malady had ceased to exist. Specific remedies in such cases did harm, but this did not prove that the original diagnosis was erroneous. Urticaria was often found with the visceral neuroses, but zona perhaps never, unless there had been some cerebro-spinal disturbance at the same time. One lady, he had seen, ceased to be troubled by angina after a sharp attack of shingles. In another case a woman suffered from visceral neuralgia, and had a zona occupying the whole length of the ulnar aspect of the arm from the shoulder to the wrist.

Coming at last to the subject of treatment he said that although the principle of all therapeutics must be a clear diagnosis, yet, on the other hand, the most elaborate diagnoses were but laborious idleness if not made the basis of treatment. We might cry out with the child in La Fontaine—

> "Eh! mon ami, tire moi de danger,
> Tu feras, après, ta harangue."

The beginning of all successful treatment must be to convince the patient of the true nature of his malady. Once convince him that the stomach was the seat of neuralgia, and that any pain caused by food was as accidental as was the increase of pain in tic douloureux during the act of mastication; once let him realise that so far from waving his dishes aside, like the physicians of Sancho Panza, we would rather prompt him to indulge as liberally as his impaired forces would permit; once persuade him to throw all the alteratives, the pepsines, and the mineral waters to the dogs, the battle was half won. He could not read the lives of men, like Dr. Quincey or Carlyle, without suspecting that a timely course of Fowler's solution would probably have deprived us of the letters of Mrs. Carlyle, and of the *Confessions of an Opium Eater*.

By commencing gradually with small quantities of light and highly nutritious food, the gastralgic would get over his dread of food, and begin to digest more. Keeping the patient in bed for a few days secured economy both of heat and of work, and often sufficed to cure a neuralgia, cold feet indeed were frequently the exciting cause of an attack. Mental worry being a prominent factor in the disease, change of air and scene always acted beneficially. Gastralgics should go inland, rather than to the sea-side, where they were apt to become irritable and sleepless. On the other hand, neurotics must avoid mountain districts, a dry sunny slope a little away from the sea-shore suited them best. The only things that must be absolutely forbidden were tea, coffee, tobacco and strong meats. Tea retarded the pulse, and gave rise to a horrible empty feeling as bad

as the pain itself. Alcohol had better be forbidden, though it might occasionally be of some service. Morphia in severe cases could not altogether be dispensed with, but it should only be used to give relief in the severer attacks of pain. Of the other drugs, arsenic was by far the most useful in the treatment of gastralgia, small blisters to the epigastrium also did good. Quinine, belladonna, the bromides and silver salts were all useful, the former especially in those not uncommon cases where there was an association with malaria. Iron did good where there was distinct anæmia present. The treatmeut of these cases by alkalies was not to be commended. Arsenic alone could be considered a specific, and rest, sedatives, nutrition and tonics, constituted the other treatment. In enteralgia, quinine and belladonna had proved themselves more useful than arsenic, but the latter also did good. In all forms of visceral neuralgia, a source of peripheral irritation should be sought, and, when found, soothed if possible. The difficulties in the treatment of neurotic vomiting were well known, he had found walnut spirit useful in some cases. The vomiting in gastralgia might be called spasmodic asthma of the stomach, and was best treated by a little chloroform, or morphia subcutaneously.

Dr. Allbutt concluded these admirable lectures with the following very modest remarks :—

"Gentlemen, I must not detain you longer. Happily free as I am from neuroses in general, yet a sinking at the heart has possessed me many a time as I wrote, and then read, the lectures I have ventured to present to you. How slender is the offering none knows better than I. Once, while I have comforted myself with the thought that the late Dr. Symonds did not think the subject of headache too trivial for your thoughts, but again I reflected how much the more must be the talent of the speaker the less striking his subject, and how great the interval between him and me. That I have said nothing new to you I am painfully aware—that my words may not have fallen below the authority of this chair is my single hope."

THE RECENT DECLINE IN THE ENGLISH DEATH-RATE CONSIDERED IN CONNECTION WITH THE CAUSES OF DEATH.[1]

By G. B. LONGSTAFF, M.A., M.B. Oxon., M.R.C.P.

One of the most striking facts of the day, from the statistician's point of view, is the remarkably low death-rate that has prevailed in this country during the last eight years. From 1838 to 1875 inclusive, the death-rate averaged 22·3 per thousand, but during the eight years 1876–83 inclusive, it has averaged only 20·3. The only approach to such a low mortality was in the five years 1841–45, when the death-rate averaged 21·4 ; so that the recent low rate is both considerably lower and extends over a greater number of years.

Mr. Noel A. Humphreys in his paper last session proved conclusively that if the English death-rate should continue at the low average of the five years 1876–80, the mean duration of male life in this country would be increased by 2·0 years, and that of female life by no less than 3·4 years, as compared with the English Life Table. Moreover, among males 70 per cent., and among females 65 per cent. of this increased life would be lived between the ages of 20 and 60 years, or during the most useful period.

At Mr. Humphreys's request I have taken up the question where he left it, and have examined the changes that have taken place in the death-rates at different ages in the two sexes "from various causes of death."

Before entering into fuller detail it will be convenient, without taking into account sex and age, to ascertain what alleged causes of death appeared to be growing more and more potent, and what, on the other hand, are less and less frequently assigned.

For this purpose we may utilise Table XXXIV. in the Registrar-General's Forty-third Annual Report. In this are given the mean annual rates of mortality for each period of five years from 1850–79. From it the following table is constructed :—

Table A.—*Rise or Fall in the Death-Rates per* 1,000,000 *Persons Living in England and Wales, from Various Causes or Groups of Causes. Averages of Quinquennium* 1875–79, *compared with Averages of Quinquennium* 1850–54.

Risen per 1,000,000 Living.		Fallen per 1,000,000 Living.	
Lung diseases	1,213	Phthisis	694
Heart ,,	696	Developmental diseases	617
Brain diseases, excluding convulsions	377	Fever	569
Kidney diseases	229	Dropsy	405
Cancer	191	Convulsions	342
Liver diseases	76	Cholera	287
Diphtheria and croup	69	Small-pox	197
Tabes mesenterica	65	Scarlet fever	173
Whooping-cough	45	Diseases of stomach and intestines	112
Rheumatism	45	Hydrocephalus or tubercular meningitis	111
Other causes	196	Sudden death—cause unascertained	101
Total rise	3,202	Diarrhœa	85
Balance, fall	1,049	Measles	64
	4,251	Other causes	494
		Total fall	4,251

This table suggests several remarks. In the first place it will be noticed that six so-called "zymotic diseases," viz., fever, cholera, small-pox, scarlet fever, diarrhœa, and measles, between them contribute a fall of 1,375 deaths per million, against which there is a set off of 114, being the rise under the heads of diphtheria, croup, and whooping-cough, leaving a net fall of 1,261 deaths per million from the principal zymotic diseases. But as the total fall from all causes is 1,049, it is evident that the deaths from non-zymotic diseases must have risen 212 per million.

The increased mortality from lung diseases is remarkable. It will be shown in the sequel that this is not to be explained by the fall in phthisis, even were that fall large enough to explain it. Doubtless, however, some of the cases (but not very many) now classed under bronchitis would have been attributed to phthisis thirty years ago ; also some cases formerly attributed to old age alone are now more properly classed under diseases of lungs, brain, or kidneys. Among the diseases of the nervous system, there is a fall under the vague term "convulsions" in the first few years of life, nearly as great as the rise under the other members of the group at later ages.

Now it is obvious that errors due to all causes, and more especially errors due to changes in nomenclature and classification, will be minimised by comparing two periods as near together as possible, and for my present purpose it is convenient to take the periods 1861-70 and 1876-80.

[Dr. Longstaff then explained the numerous elaborate tables, on which the paper was founded, and continued.]

In the examination of these tables, it will be convenient to consider those causes of death first which Table A. shows to have been long decreasing in fatality, and subsequently those which appear to have increased.

Phthisis, or pulmonary consumption, is very fatal at all ages, from 15 to 75, but most so between 20 and 55;

[1] Extracts from a Paper read before the Statistical Society, March 18th, 1884.

at ages 5 to 20 it is more fatal to females than to males, after 45 it is more fatal to men. The death-rate has declined at every age with some insignificant exceptions in both sexes; the decline being for males 14, for females 22 per cent. The lives saved amounted to 3,966 males, 6,806 females; not less than 2,685 of the former, and 4,233 of the latter, were of ages 15 to 35, that is to say, were among the most useful of the community. The question has often been considered as to how this well-known fall in the mortality from phthisis is due to "medical fashion," that is, how far it may be a mere question of classification, since it is equally well known that the mortality assigned to the diseases of the respiratory organs (principally bronchitis) is increasing. Now there are two answers to this question. Firstly, it would appear that the discovery of the so-called bacillus of tubercle, would confirm the opinions of the older writers, that phthisis is a distinct disease *sui generis*, with many forms of manifestation, and not an ill-assorted mixture of unrecognised diseases as has been more lately taught. Secondly, there is an argument that is more in place here, the mortality from phthisis is shown by the table to have diminished at the ages 5 to 35, to an extent varying from 15 to 28 per cent., whereas "at all these ages the mortality from diseases of the lungs remained comparatively stationary." This is especially well seen in Tables IVA. and IVB. I have elsewhere ("Transactions of the Epidemiological Society of London," N.S., vol. ii, p. 119) shown other reasons for believing that substantially the diagnosis of phthisis from bronchitis, corresponds with nature. We must therefore credit medicine, whether preventive, curative, or both, with another triumph here; and let it be remembered, that this triumph means saving many lives when they are most valuable. There is still ample material to work upon, plenty of room for further improvement.

Developmental diseases come next in the list of those that have decreased in fatality during the last three years. The "lives saved" number 8,425 males, 9,837 females; of these numbers, 4,346 males, and 4,372 females, are in the first five years of life, and may be fairly attributed to the better management of children, and improved sanitary surroundings, which have diminished the deaths under the vague headings "teething," "atrophy," and the like. Of the rest 2,431 males, and 3,586 female lives saved, are at ages over 65, at which period there is a large increase of deaths from "local diseases," as they are called. Diagnosis is now more accurate, and certificates are more carefully filled up, hence fewer deaths are attributed to "old age."

"*Fever*" comprises typhoid or enteric fever, now the most important by far; typhus fever, which is still prevalent to some extent in Ireland, and lingers in the Irish quarters of Glasgow, Edinburgh, and Liverpool; and some less defined diseases numerically not very important. Fever kills males and females about equally, and at all ages, the two extremes of life suffering somewhat more severely. The percentage fall in the death-rate is very remarkable, being no less than 57 per cent. for each sex, the number of "lives saved" is no less than 6,188 males and 6,510 females yearly; the salvage being greatest under five years of age, but very considerable at each age below 75. It seems impossible to dissociate this great saving of life from the operations of the Public Health Acts. The fall in the death-rate from fever is, without doubt, the great triumph of the sanitary reformers. Typhus has been driven out, from place after place, by measures taken to check over-crowding and want of ventilation (which have been, to a great extent, successful, although the pamphlet literature of the past autumn has, no doubt, caused a general impression to the contrary), until it now only lingers in the lowest quarters of a few large towns. Things are not perfect yet, far from it, but they were once much worse, and that not so long ago. On the other hand, measures directed to improve drainage and water supply have been most successful in restraining enteric fever within comparatively narrow limits.

Dropsy.—All that need be said about this is, that in 1850, 9,981, or 2·8 per cent., of the total deaths, had this cause assigned, whereas in 1880 only 3,192, or 0·6 per cent., of the total deaths were so classed. This does not mean that fewer persons die of dropsy than then, but that the dropsy itself is now more commonly attributed to its approximate cause—disease of the heart, kidneys, liver, or ovaries, or cancer. In the tables dropsy is included under "Heart Diseases," but it has now ceased to play such an important part among the assigned causes of death as seriously to affect the correctness of the returns.

Scarlet fever has dimished notably, but it is not safe to draw conclusions as to the future.

In both *small-pox* and *diphtheria* there has been saving of life, but these diseases now cause such small mortality that their total extinction would only reduce the general death-rate by 0·2 per 1,000.

The *diarrhœa* figures are confused by the occurrence of the epidemic of Asiatic cholera in 1866. There is room for great improvement under this head.

The mortality from *measles* has diminished notably, but *whooping-cough* has been stationary. Whooping-cough is much more fatal to girls than to boys. Measles causes nearly five times, and whooping-cough nearly six times as many deaths as small-pox, while the amount of mischief to be attributed to these little-thought-of ailments in the way of impaired general health, permanent lung disease, and even blindness and deafness, will probably never be known. It would appear that as yet preventive medicine has failed to control these diseases; can this be because the people will not co-operate to put down diseases which only affect young children?

Turning now to the other side of the account, lung diseases have increased in the period under consideration, among males 13, among females 14 per cent. The annual "loss of lives" amounts to 6,490 males and 5,404 females; of these 3,486 males and 2,557 females were under five years old, while 2,919 males and 2,952 females were aged 35 years and upwards.

Heart Diseases and Dropsy.—The mortality of males has increased 14 per cent., of females only 11. In both cases there has been a notable fall at the earlier ages, but a considerable increase, greatest in males, after the age of 35. Whereas 344 male and 242 female lives have been saved before the age of 20, at all ages over 20 no less than 2,909 male lives and 2,363 female lives have been lost annually in the latter as compared with the former period in the tables. Corresponding with this increase is an increase in deaths from rheumatic fever, which is a most fruitful cause of heart disease.

Brain Diseases.—On one hand, 2,443 male children and 2,227 female children that would have died annually from diseases of the nervous system under the death-rate prevailing in 1861–70, now survive under the rates prevailing in 1876–80; but, on the other hand, at ages over 35 no less than 2,098 males and 2,078 females now die that would have survived, or died of some other cause under the former *régime*.

Kidney Diseases are in both sexes most fatal in middle and advanced life; they are about twice as fatal to men as to women. Female mortality has, however, increased nearly twice as much under this head as male, although the increase is very great in all cases, varying from 20 to 81 per cent. The total loss of life from renal

*

disease amounts to 1,702 males and 1,417 females, mainly in middle and advanced life.

Cancer, in contrast to renal disease, is twice as fatal to women as to men; is rare in early life, but steadily increases in frequency from the age of 25 upwards. Cancer has increased 38 per cent. in males, 24 per cent. in females, the greater increase in males being probably due to the fact that cancer of the stomach and liver, which is commoner in men than women, is much more difficult of diagnosis than cancer of the female breast or of the uterus. Hence improved medical skill affects the returns for it more. The loss of life due to the increased mortality from cancer amounts to 1,187 males and 1,661 females, of which seven-eigths are above the age of 45. A recent writer[2] said he was convinced that the long-continued and steady increase of cancer was not apparent only, and accounted for by increased accuracy of diagnosis and registration, but was an undoubted fact; the cause is quite unknown, but must probably be sought in some abnormal circumstances of our artificial existence. It should be remembered that very few, if indeed any, recover from this much-dreaded disease, and also that it chiefly attacks after the reproductive age is past. From these facts we may draw the consolation that if there are many killed, there are no wounded, and that although the tendency to cancer may be handed down to offspring, they are not born enfeebled in consequence of their parents' ailment.

As regards other diseases, I will only remark that with trifling exceptions there is more or less gain of life under each division of each zymotic disease; also that the increased number of deaths from violence at the higher ages, accompanying a diminished death-rate at the lower ages, is a curious fact that is difficult to explain.

[Dr. Longstaff then discussed at considerable length the effects which these modifications in the mortality of this country might be expected, if continued to exert, as, (1) the duration of life; (2) the sex and age distribution of the people; and (3) the rate of increase of the population; and he concluded his paper with the following inferences, drawn from the facts under review.]

(1.) The decline of the death-rate in recent years is chiefly to be attributed to a diminished number of deaths assigned to fever and phthisis, and in a somewhat less degree to scarlet fever, diarrhœal diseases, small-pox, diphtheria and measles.

(2.) There is also a great diminution under the heading "all other diseases," but this is largely to be explained by greater precision in filling in certificates of the cause of death, which partly accounts for the increase under certain other causes.

(3.) There has been coincidently, with a fall in the general death-rate, a considerable increase under certain causes of death, notably diseases of the lungs, heart, kidneys, and cancer.

(4.) The figures prove that only a portion of the increase noted under the above headings, can be explained by improvement in the returns. There has been a real, not merely an apparent increase. More especially the increase under lung diseases will not explain the fall under phthisis.

(5.) The gain under phthisis is more important than the loss under cancer, kidney diseases, and some others, since the lives saved are more valuable than those lost, also in the case of phthisis, parents beget children when far advanced in disease, a fact greatly to be regretted.

(6.) Preventive medicine should be especially directed against those diseases which kill the largest numbers, such as "local diseases" generally, the ill-defined diseases of infancy and phthisis; while among the zymotic diseases, diarrhœa and scarlet fever, whooping-cough and measles, are more important than diphtheria and small-pox.

(7.) Since the falling causes of death can only fall to zero, but the rising causes may rise indefinitely, the present changes may in course of time lead to a rise in the general death-rate.

(8.) The tendency appears to be for useful working life to be increased, but for old age to be slowly shortened.

(9.) The increased mortality in the latter years of life, and such phenomena as the increase of defective sight and rapid deterioration of the teeth, probably result from the increasing proportion of the population living under the artificial conditions of town life.

(10.) The present increased mortality at the higher ages cannot possibly be explained by the recent diminished mortality at the beginning of life, even on the supposition that the survivors are more delicate.

(11.) The changes that are taking place in the incidence of mortality almost all aid the other causes which contribute to the great superabundance of women in England and Wales.

(12.) They also tend to increase population both by diminution of deaths, and increase, positively and relatively, of births.

LIFE AT SEA—MEDICALLY CONSIDERED A CRITICISM.

By ROBERT WILLIAM PARKER,
Surgeon to the East London Hospital for Children.

As one who firmly believes in the efficacy of the "exhilarating and fresh breezes of the ocean," I venture to offer a few friendly criticisms on the article "Life at Sea," which appeared in a recent issue of the *Medical Times*.

Like Dr. Hughes Bennett, I also have served "in an official capacity" at sea, but let me add at once, that my experience—though much more recent—is not so wide nor so long as his. This, in his opinion at least, may perhaps account for that divergence in our views, which it is my purpose now to express. I will take the points raised by Dr. Bennett *seriatim*. And first, as to the general advisability of "taking invalids from the comforts and luxuries of home." This is always a very grave question, whether the object be a sea-voyage, a journey to Egypt, the South of France, or any so-called health station; where the one is warranted, and undertaken on adequate grounds, and *under suitable medical authority*, the other in my opinion may equally well be allowed. It is not the unsuitability of life on board ship on the one hand, or the fatigue of a long journey overland on the other, which is responsible for the disasters that attend both practices, so much as the sending away of patients who would be far better at home, both for individual and for general reasons.

In reply to the general question, *Is life at sea a healthy one?* I should unhesitatingly say—Yes. I would further assert, that if sailors are not healthy, the fault lies not in the occupation, so much as in their mode of life, when *out of occupation* on shore. Sailors who lead steady lives on shore, acquire a vigour of constitution such as only few landsmen attain to. I am ready to admit that there are, or have been marked shortcomings in the diet, and sleeping accommodation supplied in some ships; there are, or have been, cases of hardship on board; but these are not necessary evils, so much as the accidental results of insufficient

legislation; they cannot at any rate be used as evidence in the main argument before us—the advantages of a sea-voyage for invalids. I should be quite willing to admit that there are certain quarters of the globe, where special dangers lurk; the mouths of certain rivers on the West Coast of Africa for instance; but even here the men often suffer, because they fail to observe those precautions which experience has shown to be needful; invalids would naturally avoid such localities.

The great failing of sailors is too much liquor while "on shore." If they would but abstain altogether from alcoholic drinks, *or drink in moderation*, there would be much less sickness among them, and less need, at the end of every voyage, to weed out the crews as is now done. Sailors can no more afford to trifle with their health and strength than their less favoured brethren on land. The sleeping accommodation in the "fo' castle," is certainly not always very first-rate; on the other hand, the sailor's "turn-in" is short, and the rest of his time is spent on deck, in an air such as we cannot get in London at any price. As regards his food, changes of temperature, &c., is a man in the same social position better off in the slums of Liverpool or London? As to the mortality statistics, it must be borne in mind that not all those who call themselves seamen are real sailors; many are ne'er-do-weels, who have tried many occupations without success, and for the reasons already hinted at. We must carefully analyse the figures, not only on these points, but also as to cause of death. I have a firm belief that a sailor's life is *per se* a very healthy life, and will contrast favourably with any other occupation of the same social stratum. But even if it were not, could Dr. Bennett apply the argument to the main subject under discussion?

Dr. Bennett himself points out many classes of persons who "would be greatly benefited by a trip for a few weeks in a yacht or a sailing vessel." I agree with him thus far. For an overworked professional man, as an escape from the wear and tear of business life and excitement, as a rest after late hours or too much dissipation, I consider a sea-voyage as unequalled in its power of restoring health and nerve. But I would even go further, for I think there are many persons suffering from "incipient phthisis," who would benefit immensely from a voyage of from two to four months, *in suitable latitudes*, and *in suitable seasons*. The case suggested by Dr. Bennett, as an example, seems to me to be just such an one as would benefit. We have a patient with incipient disease, on board a first-class ship, supplied with every convenience and comfort, an experienced surgeon to attend him, and *wealth* to procure every desirable luxury. Such a patient need not share his cabin with any one; many ships, indeed, are so constructed that two cabins can be turned into one large state-room, it being only a question of money. The free ventilation referred to, is a strong recommendation rather than a drawback; the "exposure of every kind, sudden change of temperature and climate, extremes of heat and cold, ... " obtain to some degree, but not more so than on land, even in the favoured localities frequented by invalids. Of course I am referring to a well-selected voyage, as for instance, to the Cape and back, or to Australia and back, by way of the Cape, or indeed by way of Suez, and in a good steamer. The picture drawn by Dr. Bennett, is the reverse of what I myself experienced. Within a very few hours, a good steamer leaves the cold, bleak, sunless atmosphere of the fiftieth degree of latitude behind, and steadily approaches the warmer degrees, with their bright clear atmosphere and, often for weeks together, almost unbroken sunshine. On board the large translantic steamers, which ply between England and the Cape, and the Australasian colonies, any and every luxury can be had by those who have wealth; fresh vegetables, fresh milk, fresh meat, and poultry, are freely provided for all—not merely for invalids, but as part of the daily bill of fare, and choice wines and good fruit are as easily obtained as on land. The saloons are luxuriously furnished and large; they are frequently decorated with gorgeous sub-tropical flowers, which are taken on board at some of the stopping places *en route*. The coaling of a steamer is certainly a disagreeable performance; fortunately this does not occur very often, and only lasts two or three hours each time. If a patient were too weak to go on shore, he might shut himself up in his cabin, and would then escape the dust at least, if not altogether the noise and bustle incidental to this dirty, but very necessary operation. The amount of rain and damp varies much with the season, but most ships are now provided with saloons, smoking rooms, or a music room on deck, where passengers can while away their time, should the weather preclude open air exercise on the quarter deck; there is a good library of books on general literature, as well as light reading in the form of novels, for the use of passengers; there are many other ways of passing time, such as concerts, private theatricals, readings, and dancing; scarcely a day goes by without some incident to break what Dr. Bennett describes as the "monotony about a life at sea." The study of the ship's log, the interchange of signals with passing ships, the ship's daily run, the presence of some unusual birds, all trifling incidents, are nevertheless amusements, which prevent an ordinary, well-balanced mind from any sense of *ennui*. The study of one's fellow passengers, their adventures in life, their accounts of new countries, their views of persons and things, the contrast of colonial ideas with those of the old country, are in themselves a source of much pleasure and information. The admirable arrangements of a ship, the punctuality, and orderly conduct of all the officials, strike one, and the vast amount of information which the officers accumulate, renders contact with them during a voyage, instructive and agreeable.

As regards the "horrors" and "discomforts," incidental to the keeping clean of the decks, working the cargoes, and the vibration of the engines, I will only say that a few days serve so to accustom passengers to it, that they sleep through it all. The following incident will serve to illustrate this point. On a voyage home from the Cape, a valve gave way one night, and the engines had to be stopped about midnight, in order that the valve might be repaired. What was the result of this unexpected cessation in the vibration of the engines? The passengers could not sleep, and all came on deck to see what was the matter! I made great fun out of this, and whenever a passenger subsequently referred to the noise of the engines, the little incident I have related was used, and a laugh obtained at his expense. The noise and vibration of the engines are, however, elements of discomfort too real to be ignored. On this account, in the newest ships, the state rooms and saloons are all built either amidships, or even still more "forward," and thus noise, heat, vibration, are reduced to a minimum. This class of ships takes out one or two milch cows, a quantity of live stock for the supply of fresh meat *en route*, as well as a number of fowls, geese, ducks, with which to vary the ample meals, admirably cooked, and well served in a spacious saloon: these form in themselves no inconsiderable source of pre-occupation; mineral waters, choice wines, ale and stout, are all obtainable. I fail to see what more an invalid could get, or could wish, on land even in a favoured locality.

In contrasting a voyage in a good ship with a railway journey, I was immensely struck with the

obvious advantages of the former. On first going aboard, one's cabin is put in order, and a few cabin ornaments hung about, goods and chattels are suitably arranged in the manner one is *accustomed to at home;* there is subsequently no further trouble until the end of the voyage, everything one can wish is at the command even of moderate means. Nor must I forget the morning bath or douche in water fresh from the ocean —a great treat, and one worth a considerable amount of inconvenience. How different is this from the din and hurry of railway travelling, the dust and dirt, the confinement for hours together in a close stuffy carriage with strangers, the constant stoppages, the badly prepared food, and all the other evils too well known to need recapitulation.

Of course, an invalid would not undertake a voyage alone; while the wealthy, in addition to a friend or two can take their own servants, or a trained nurse to attend on them during a voyage. There is one drawback, referred to also by Dr. Bennett, but not so prominently brought forward as I think it deserves: I mean sea-sickness. For a very few, this is a serious drawback. I think about two per cent. of all passengers suffer more or less the whole voyage. Should an invalid, unfortunately, belong to this minority it would be a most disagreeable *contretemps.* Curiously enough, in my experience, weakly invalids are often exempt, while strong-looking people succumb; with the generality of passengers sea-sickness passes off in about 24 to 48 hours. Children are singularly free from sea-sickness. In one of my voyages I brought home an invalid lady; it was doubtful whether she would be able to bear the voyage; events proved that beyond a little nausea for about 24 hours, the sea had no effect upon her; but her nurse, a powerful woman, was ill for several days. It is desirable to provide a store of aperient medicine. Troubles at sea among passengers frequently depend on constipation due to the want of exercise. Dr. Bennett refers to this lack of exercise. Something may be done by pacing the quarter-deck systematically every day. But a bottle or two of some aperient bitter water, of which a dose should be taken two or three times a week, will well repay the outlay, and the trouble entailed in packing it.

I need not say more on the special question; but I would enforce the desirability of not undertaking either a voyage or a journey in search of health without good reasons, and without the help and advice of those who have really studied the question. I think Dr. Bennett's estimate of the "discomforts and deficiencies" of a voyage is probably a correct one for voyages as they were fourteen years ago; but I venture to think that all the conditions have now been thoroughly changed. They are just as much changed as the ships themselves, and fourteen years have brought about remarkable alterations in all that concerns marine architecture and economy. A voyage to the West Indies, or to Australia, or to the Cape, can now be made in splendidly fitted ships; and those who possess wealth can have as many comforts on board—provided they are not hopelessly bad sailors—as are to be obtained on *terra firma.*

German Students in the Summer Session of 1883. —The *Breslauer Aerztliche Zeitschrift* states that the following are the statistics of the German Universities for the summer of 1883:—Berlin, 4,062; Bonn, 1,165; Breslau, 1,559; Göttingen, 1,104; Greifswald, 741; Halle, 1,414; Kiel, 441; Königsberg, 929; Marburg, 848; Münster, 328; Erlangen, 641; Freiburg, 823; Giessen, 464; Heidelberg, 1,019; Jena, 631; Munich, 2,295; Strassburg, 834; Würzburg, 1,085; Leipzig, 3,097; Rostock, 231; Tübingen, 1,373. Of these 25,084 students, 6,172 were students in Medicine, 9,117 in Philosophy, 5,626 in Jurisprudence, 3,558 in Evangelical Theology, and 811 in Catholic Theology.

THE TREATMENT OF GRANULAR LIDS, ENTROPION, TRICHIASIS WITH PANNUS, NEBULOUS AND ULCERATED CORNEÆ.

By J. ROCHE, M.D., Mount Clarence, Kingstown.
(Retired Surgeon, Bombay Army.)

In the winter of 1875, Mary A. H. Y., a builder's daughter, of about 23 years of age, presented herself to me with the affections of the eyes, designated by the superscription of this article. She had suffered from delicate sight since her childhood, and in the year 1872 had contracted a severe cold, which apparently induced conjunctivitis and ophthalmia tarsi on both sides. She had recourse, after some time, to medical advice, was more than three months in hospital, and attended an eye-hospital for nearly six months as an out-patient. Drops were put into her eyes, blisters were applied to her temples, and counter-irritants were used over her brows. Her lids were everted and touched with bluestone, and also with a caustic solution respectively, for long periods. She is well acquainted with them, as she will never forget the pain attendant on their use, she states. When I saw her she had the striking and general appearance of a strumous unhygienic constitution, a greasy countenance, puffed lips, dwarfed nose, and knitted forehead. Her appetite was bad, and her tongue yellowish, indicative of nervous exhaustion. The conjunctivæ of both eyes were purplish red, the lids were granular, thickened and entropic, trichiasis was well marked, the lashes pointed in all directions, and their origin from the tarsi was exceedingly irregular. Both corneæ were vascular, the right almost to pannus; it had a large ulcer in the lower segment; the left had wide-spread superficial nebulæ. The patient had very little sight in the right eye, had intolerable photophobia in both eyes, and had a racking pain in the temples and brows, especially at night. The presence of light was so irksome that she had confined herself in a dark room for months, which no doubt contributed to reduce her state of health to the low grade it presented. I extracted the hairs from the lids, as being an immediate cause of irritation to the corneæ and conjunctivæ. I ordered an ointment composed as follows: Ung. Cetacei, Ung. Hydrarg. aa. ℥ss. and Pulv. Opii. gr. xxx., to be applied thickly on the outside of the lids, and over this a poultice made from washed bread, and saturated with infusion of oak-bark, to be laid over the eyes every night, and the oak-bark infusion to be used through the day with a linen bandage. She took internally Tr. Laricis ℥. x. Liq. Arsenicalis ℥. ij. Infusi Quassiæ ℥i. three times a day. The improvement was slow but well marked: the lids did not cling together so tightly in the morning, and the light became less offensive. She had cod-liver oil and syrup of iodide of iron. When the eyelashes returned in entropic manner they were extracted. The improvement was steadily progressive, the lids gradually thinned, the exuded and semi-organised sub-mucous lymph—the cause of the granular appearance and of the inverting of the lids and hairs—became absorbed, and the natural and normal condition was approached, the corneæ resuming their transparency excepting that a leucomatous spot supplanted the ulcer on the right. The conjunctivæ regained their clearness, and the eyes lost their ferrety look. Nearly six months were required for the cure.

During the last eight years the subject of this history has been well, with the exception that there is a slight superficial nebula in the situation of the former corneal ulcer (and I have no doubt from its superficiality, that the occasional stimulation of a few drops of vin. opii

would remove it), and that whenever she gets a cold, the lids become tender, which is remedied by the ointment, which, I may mention, needs warming in a porcelain spoon.

The mucous membrane lining the lids and covering the eyes is somewhat analogous to that of the bladder. Both are subject to periods of rest and motion, and to have in contact with them saline secretions, which in a healthy state do not irritate, but in an inflamed state do. Inflammations in both are attended with submucous lymphy exudations which thicken, contract, and deform the structures. Rest, anodynes, emollient astringents and the prevention of the lodgement of the hurtful excretions are the remedies for diseases in either of them.

To dissect away the roots of the eyelashes, or to cut off a portion of the outer skin under the brow, is merely combatting a symptom, not counteracting the cause, and is therefore utterly unsound treatment in entropion. To vary the inflammation by solutions of vegetables (jequirity), animals (cantharides, pus), metallic salts (copper, iron, &c.), acids or alkalies, the difference between which is rather in degree than in kind, may be successful in a manner by substituting a more vigorous and a more controllable state in granular lids, but to attack the pathological cause is a different thing. The injection of the bladder and uterus with irritant astringents in catarrh of these organs is now merely obsolete treatment. The speedy removal of phlogistic excretions and the use of emollients, anodynes, and tanno-gallic injections are to be preferred. I trust that a similar course will be adopted ere long in affections of the mucous coat of the eyes and lids after a rational system.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

WESTERN INFIRMARY, GLASGOW.

CASES OF RADICAL CURE OF HERNIA.

By G. BUCHANAN, M.D., F.R.C.S. Edin.,
Professor of Clinical Surgery, University of Glasgow.

For several years I have discontinued Mr. John Wood's operation, even in the adult, and have performed an operation identical with that which I introduced for children in January, 1879. The following recent cases may be given in illustration.

Case 1.—W. D., aged 30, came under observation on February 15th, 1883. He was strong and healthy, but had suffered from a reducible inguinal hernia on the right side for ten years. The hernia is not very large (about the size of a turkey's egg), and has hitherto been easily reduced. It can be kept up by a truss, but his experience is that every now and then, notwithstanding every precaution, it comes down on any considerable exertion, and sometimes it takes some trouble to reduce it. In these circumstances he came to me to ask if something could be done to enable him to dispense with the truss, and insure his safety. I told him that I believed the radical cure could in his case be performed safely and effectually, but I also frankly said, as I always do, that no such operation could be done without some risk, and it was for him to decide whether or not he would accept this risk, with the prospect of a fortunate result.

The operation was done by making an incision along the sac, the bowel being retained within the abdomen by the finger of an assistant placed on the external ring. The sac was separated from the cord, a catgut ligature was tied tightly round its neck on the ring, and the pillars of the ring drawn together tightly by silver wire, which was introduced by a nævous needle. In passing the needle through the internal pillar of the canal care was taken to include the lower edge of the conjoined tendon, as is done in Wood's operation. The wound was treated antiseptically.

It is needless to detail the particulars of the after-treatment. Some inflammation, granulation, and slight discharge occurred, but the result was perfect. At this date (March 10th, 1884) not a trace of the hernia is visible.

Case 2.—G. M'N., aged 55, admitted to the Western Infirmary, Glasgow, September 26th, 1883. History: 26 years ago, after a kick in the groin from a horse, a swelling appeared and continued to increase, and for this he wore a truss, with not much relief, as he was never able to get the tumour entirely away. On the day of admision it could not be even diminished in size, and his medical man could not reduce it. On admission there was a large ovoid tumour in the right groin, elastic, tense, doubtfully fluctuant, not tympanitic. Vomiting had occurred several times, but not severely. I put the patient under chloroform, but though the tumour got smaller and less tense, there was no gurgling, and no feeling of any part having receded. There was no testicle in the right side of the scrotum, and I was led to think that it might be a hydrocele of the tunica vaginalis of an undescended testicle. I left the patient till next morning, as the vomiting was not urgent or even bilious.

Next morning I again put the patient under chloroform. Prof. Humphry, of Cambridge, who was in Glasgow as President of the Sanitary Congress, was present. On cutting into the sac, it proved to be, as I anticipated, a hydrocele in the inguinal canal; but behind the testicle which occupied the lower end of the canal there was a knuckle of dark red bowel, which was strangulated by the neck of the sac, near the internal ring. This I divided, and returned the bowel. The testicle being very small I removed it, and after that sewed the pillars of the ring together, as in the last case, with strong silver wire, clipping short the ends, and leaving them at the bottom of the wound.

Recovery was tedious, owing to the amount of granulation to fill up the cavity from which the testicle was taken. But the result was perfect cure of the hernia.

Remarks.—It is unnecessary to detail other cases, of which I have had many; the result of my experience is as follows:—Many years ago I used to perform the operation of Wütz er with the plug, which was much advocated by Sir Spencer Wells, about 1858 or so, but I was not satisfied with its results. After Prof. John Wood introduced his operation with the wire, I adopted it, being satisfied with the accuracy of the anatomical principles on which it was based. But it was not suitable for the cases in which I desired to use it most, viz., in children. His operation with pins I did not find suitable, as indeed he himself admits. So in 1879 I performed the operation described in this paper, and was so satisfied with the results that I see no reason why it should not be adopted in the adult, as Mr. Banks of Liverpool, and others, besides myself, have done. Mr. Spanton's operation with the screw I have no experience of, not having met with a case in which I deemed it likely to be preferable to the one I adopt, and I incline to believe that the retention in the tissue of the wire, which binds the columns together, is probably more likely to resist any tendency to future descent of the hernia, than agglutination by fibrous tissue alone.

Medical Times and Gazette.

SATURDAY, MARCH 22, 1884.

The agitation against overwork in schools has increased, is increasing, and ought to be carried on until decided and satisfactory means are adopted to prevent the evil complained of. But many of the cases brought forward as illustrations of this evil are very weak and imperfect; and not a few break down altogether under enquiry. The Vice-President of the Committee of Council on Education was questioned in the House of Commons on Thursday last week about the case of a boy who was reported to have died from over-pressure of work at a school in Wolverhampton. One of Her Majesty's Inspectors had been sent down to enquire into the matter; and it appeared that the medical man who attended the child, a boy of seven years of age, had said he "died of brain fever, the exciting cause of which was school work." But there had not been any inquest, nor had a *post-mortem* examination been made; and Her Majesty's Inspector learned that the child's chief complaint had been that his throat was sore; and it was shown that he had not had any home lessons; and that though he lived near the school, and his teacher frequently passed by his house, his parents never made any complaint about his health, or of the work he had to do. The boy had not long before passed the first standard; and most people will agree with Mr. Mundella that it does not seem possible the child had been overworked. It should be remembered that mistakes like this, injure the cause they are meant to support. Unintelligent zeal is always mischievous.

The ruling of Mr. Justice Stephens as to the legality of cremation, as a mode of disposing of dead bodies, has naturally excited much attention, and questions have been put in the House of Commons, to the Home Secretary, on the subject. It will be remembered that Mr. Justice Stephens declared that he could not say cremations were illegal, in cases where medical certificates had been given that death had resulted from natural causes, provided the process of cremation had been conducted so as not to cause a public nuisance, or to provoke a breach of the public peace. Sir William Harcourt, in reply to questions put by Mr. Labouchere and Dr. Cameron, declined to give any opinion on the matter as respects the legality of the practice; but said, that as far as it concerned him, as an administrative officer, he could not in any way encourage it. He believed the practice to be repugnant to the general sentiment of the people; and that it might, in cases like the Liverpool poisoning case, become an obstacle to the detection of crime. In this latter belief, the Home Secretary is unquestionably right—it constitutes *the* objection to the adoption of cremation as a mode of disposing of our dead; but he avoided expressing an opinion as to whether he has, or has not, any power to prevent or effectively discourage the practice.

An unusual number of patients and ophthalmoscopic drawings were exhibited at the meeting of the Ophthalmological Society last Thursday week, as will be seen by a reference to our report of the evening's work, which appears in another part of this issue. Even with the greatly improved accommodation that the building operations of the Medical Society last session have provided, the opportunities for examining the patients were not all that could be desired; and as this feature of the exhibition of living specimens is a very important part of the Society's work, it would be a matter for regret if its utility in this respect was in any way impaired.

There were also several communications of interest. One by Mr. Snell, on two cases of Retinal Glioma. Mr. McHardy described, and strongly recommended, his operation for chronic primary glaucoma, advocating a large iridectomy. He was followed by Mr. G. E. Walker, who advised an almost exactly opposite line. Dr. Gowers read a short but very interesting paper on cases of Spasm of the Ocular Muscles; and then Dr. McKeown introduced the important subject of the means to be adopted to diminish the number of cases of blindness from ophthalmia neonatorum; this led to the appointment of a committee to consider and report upon the whole subject. Dr. A. H. Benson brought to a close a long meeting with some observations on jequirity.

A paper, by Dr. S. West, upon Multiple Abscesses in the Liver, at the Clinical Society's Meeting, on Friday, March 14th, gave rise to a discussion of some interest. Numerous cases were cited of hepatic abscesses owning no primary cause outside of the liver itself, and yet, in many instances, small and numerous. The hard-and-fast line that has been drawn by some authors between the single simple abscess and the multiple pyæmic variety is thus rudely broken through, and there would seem to be every reason to believe in the occurrence of multiple abscesses of idiopathic origin; the great clinical distinction being, that the latter variety admits of perfect recovery. With regard to the symptoms of hepatic abscess and their respective diagnostic value, various opinions were expressed. The experience of surgeons would appear to be in favour of tapping all such abscesses below the margin of the ribs rather than through the intercostal spaces.

The subject of the treatment of foreign bodies impacted in the œsophagus was introduced by a concise account given by Mr. Butlin of a case, in which he had been compelled to perform œsophagotomy for the removal of artificial teeth firmly fixed in the œsophagus, and almost completely obstructing it. The necessity for the operation is happily very rare, although the occurrence of accidental swallowing of artificial teeth would seem to be almost common. Several speakers were enabled to bring forward cases, and the opportunity was not lost for the relation of several interesting anecdotes bearing upon the subject. A typical case of Myxœdema was exhibited by Dr.

James Anderson ; and several examples of perforating ulcer of the foot and dislocated patella, a list of which we append elsewhere.

Neurology was rather the order of the day at the Pathological Society's meeting last Tuesday, no less than four of the communications dealing with this subject. Unfortunately none of them can be considered as aiding much in the great question of cerebral localisation. In Dr. Pye-Smith's case, for instance, with the utmost deference to him, we cannot see that there is any good reason for refusing to attribute the paresis of the arm, the ptosis, and the optic neuritis to the tubercular meningitis. We are inclined to believe that it is very nearly impossible to say how long a tubercular meningitis may have existed merely from the *post-mortem* appearances.

Dr. Ormerod's case was hardly sufficiently free of complication to be relied upon as indicating the centre for hearing, and the same may be said of Dr. Ilott's. Drs. Morrison and Turner showed a case of "Porencephalie," the chief interest of which was its extreme rarity. Mr. Makins's case of pressure on the trachea by caseous mediastinal glands is certainly one of considerable rarity, caseous glands after measles being one of the most common experiences in the wards of a children's hospital, and this region being their favourite seat, but for them to lead to such serious dyspnœa as they gave rise to in this case is very exceptional, and indeed probably almost unprecedented, in this country at any rate.

At the annual meeting of the Royal Medical and Chirurgical Society on March 1st, 1884, it was resolved —"That in recognition of the moral worth of the late Mr. B. R. Wheatley, and in gratitude for his devoted services to this Society, as its librarian, for nearly forty years, a subscription be opened among the Fellows of this Society, to which the Members of the Pathological and Clinical Societies and the Fellows of the Obstetrical Society shall be invited to contribute, in order to extend the provision which Mr. Wheatley was able to make for his sister and niece ; and that a Committee be named to carry out this object, which the Presidents of the Pathological, Clinical, and Obstetrical Societies shall be invited to join." An account has been opened for the "Wheatley Memorial Fund" with the Union Bank of London, Argyll-place, Regent-street, London, W. The Presidents of the various Societies have taken up the movement cordially, and the following Committee has been appointed, viz. :—Dr. George Johnson, President of the Royal Medical and Chirurgical Society ; Mr. J. W. Hulke, President of the Pathological Society ; Sir Andrew Clark, Bart., President of the Clinical Society ; Dr. Gervis, President of the Obstetrical Society ; Mr. John Marshall ; Mr. Cooper Forster, Treasurer ; Mr. Savory ; Dr. Wilson Fox ; and Mr. Berkeley Hill, Honorary Secretary.

The Council of the Clinical Society have resolved to subscribe the sum of twenty-five guineas to the Fund, and the example thus set by the Society as a whole will doubtless be followed by the individual members who compose it, in order to provide a fund worthy of its object and, in the words of Sir Andrew Clark, "equal to our means, if not to his merits." The unvarying courtesy and untiring zeal which endeared the late Mr. Wheatley to all members of the older Society have been already acknowledged in many ways, but no more graceful mode of recognising his important services to the other Societies which meet in Berners Street could be adopted, than the establishment of a fund under the auspices of the respective presidents, with a view to the purchase of an annuity to extend the provision which he had been enabled to make for those hitherto dependent on him. A cause such as this needs no advocacy.

The adjourned debate on Sir W. G. Hunter's report on the cholera in Egypt, having ended in a way that gave satisfaction to neither side, the Secretary of the Epidemiological Society requested Dr. Geo. Gulliver to reopen the subject last week. This he did in an able and remarkably modest paper, treating the whole question of the ætiology of cholera in an impartial and truly scientific spirit. After enunciating the several views held by different authorities at home and abroad, he proceeded to discuss the evidence for and against (1) the theory of direct contagion, (2) that of atmospheric and telluric influences, which he called the Indian theory, and (3) that most favoured in Germany, which refers cholera, enteric and yellow fever, and some other diseases, to a class of transportable miasmata. This is the view which we have throughout advocated, though without committing ourselves to the refinements and speculations with which some of the Munich school have surrounded it, and which are as yet but hypotheses, unproven if not incapable of proof. We do not think that Dr. Gulliver did full justice to this theory, or indeed, fully understood it, appearing to lay too much stress on the associations suggested by the word miasm, which he seemed to consider as synonymous with malaria proper. His arguments, however, in favour of the communicability of cholera, of contagion in some sense of the word, were so able, so fair, and supported by such a mass of facts drawn from the history of cholera, in England, India, America, and Egypt, as to elicit the heartiest expressions of appreciation, even from those whom they failed to convince. Indeed, no one could refuse to admire the thoroughly scientific tone of the paper, which we hope to reproduce more fully, and the entire absence of dogmatic assertion.

Surgeon-General Comyns, who was at Malta in 1865, was able to explain the oft-repeated paradox of the outbreak of cholera in that island, while the strictest quarantine was maintained, by showing that the first cases occurred on the shore of the quarantine harbour, the tideless and stagnant waters of which were fouled with the choleraic excreta from the infected ships. The Governor, discrediting the nature of the disease, withdrew the cordon which Dr. Comyns had established, and cholera soon appeared on the opposite shore of the harbour. Here, close to the mouth of a sewer, the 22nd Regiment embarked on board the

Simoon *en route* for Gibraltar, and the disease broke out among the men on the voyage. The neighbouring island of Gozo remained free while the cholera was raging at Malta, until the quarantine at first rigidly enforced had been evaded.

But the most brilliant illustrations of the modes in which cholera is propagated, were furnished by Sir William Smart, K.C.B., R.N., who told how the French troops at Varna returned from a march into the Dobrudsha smitten with cholera, and encamped on a plateau, through which ran a stream, from the mouth of which the English admiral's ship and others obtained their water, while higher up the French soldiers were washing their soiled clothes. The flag-ship lost 140 men, but Sir William's, which had brought a supply of pure water from Corfu, remained perfectly healthy except once, when moored near the shore while the wind was blowing strong from the French camp, a single case occurred. At his suggestion, the captain took her straight out to sea, and no other case appeared on board.

The series of scientific debates on the cholera has probably closed for the present, and in reviewing them it is clear that they have not been very productive of definite results, for the temptation to deal with personal experiences and curious anecdotes seems a difficult one to resist. These, though always more or less interesting, are usually more or less contradictory; thus a meeting comes to an end before any attempts can be made to extract, from evidence brought forward, such points of special value as may form the basis of suggestion for research in fresh directions. The discussion which followed Dr. Gulliver's paper was in the main no exception to the general rule. Each speaker was rich in narrative, poor in suggestion as to how his narrative might be applied for practical good, and, in some cases, the experiences were too involved to admit of being clearly followed by those to whom they were addressed. Negative results must be expected from meetings of this kind, until speeches are strictly limited in time, and directed into the main road when they wander into by-ways and alleys. A few remarks, well to the point, open up the field for reflection and are really worthy of more attention than the lengthy speeches to which we have referred: ten minutes should be the outside time allowed, and even that might be reduced, where the discussion is limited to an hour, and many members are present. Dr. Norman Chevers, the President, in thanking Dr. Gulliver for his paper, spoke of the loss sustained by the profession and the world at large through the death of the late Mr. Gulliver, and made a graceful reference to his being worthily represented in his son.

Gay with shamrocks, but oppressed by the proximity of Parnellites in the same building, the Irish Graduates' Association dined at the Holborn Restaurant on Monday last, under the presidency of Professor G. F. Yeo. Numerous distinguished guests were present, among whom we may mention Sir Joseph Lister, Sir Andrew Clark, and Dr. George Johnson, the new President of the Medico-Chirurgical Society. Sir Andrew Clark, in spite of his "surprise and consternation" at being expected to speak, was very happy in his allusions to the objects of the meeting, the gradual fusion of three nationalities to form one people "blended together for the good of nations." Other speakers were—Dr. Hare, Dr. William Stokes, the President Elect, Dr. Macnaughton Jones, and Dr. Thompson, the Treasurer.

The first dinner of the newly established Aberdeen University Club will be held on May 21st, under the presidency of His Grace the Duke of Richmond and Gordon, K.G. At a special general meeting of the Club, held at the Inns of Court Hotel, on March 12th, Surgeon-General Sir W. Guyer Hunter, in the Chair, the Rules, as revised by the Provisional Committee, were unanimously adopted. The number of members already enrolled augurs well for the future success of the Club. The Honorary Secretaries are Dr. R. W. Burnet and Mr. R. M. Routledge, from whom any information with respect to membership, &c., may be obtained.

Deputy-Surgeon-General Veale, M.D., at the Parkes Museum recently delivered an able and suggestive lecture on the organisation of field hospitals. He began by quoting the judicious counsel of the late Dr. Parkes, that just as the individual soldier during peace is drilled and trained for war, so should the various departments of an army, and especially the medical department, so utilise the time of peace, that on the outbreak of war, they may be able to put in action all those measures which are needed to maintain the troops in health, and to minimise the effects of disease or injury when these occur. He said that Dr. Parkes had been more especially led to the study of hygiene, after seeing our armies, which "in courage, drill, and discipline, had never been surpassed," embark for the East, and return at the end of a few months reduced to insignificance and impotence; not by the shot or sword of our enemies, but "by the starvation, the misery, and the disease which were due to the insufficiency of our military system." Military hospitals had undergone many and important changes since that time, the "regimental system" having been abolished, and the unification or general hospital system substituted for it.

But while this was an improvement for the hospitals, unfortunately it had somewhat interfered with the friendly understanding which had till then subsisted between the combatant and the medical officers. To some extent this was a result which might have been anticipated, for the army, said the lecturer, was eminently a conservative institution, and it was natural that its officers should wish to retain in the combatant ranks all those privileges of power and authority of which they had the traditions and the *prestige* from the feudal times. He thought, even now, that the majority of military officers were of opinion that they could manage the hospitals better than the medical officers, although if we looked back, it could not be doubted that when the specially military authority was supreme

(as at the commencement of the Crimean war), the results of that form of hospital management were highly disastrous both to the army and to the nation at large; whereas with every increase of medical authority in our subsequent military expeditions, there had been greater efficiency in the hospital administration, more effectual preservation of the health and lives of the soldiers, and, as a consequence, greater economy. He advocated, therefore, still larger powers for the medical officers.

The subject of the soldiers' food was next referred to. He believed the daily ration of meat was insufficient, and he thought the present system of giving the chief part of the food at the dinner hour injudicious, as there was nothing but tea or coffee, and a little bread with or without butter for the morning and evening meals, which, for young and growing men, was not a sufficiently supporting diet, and this led to a frequent recourse to alcoholic stimulant which was prejudicial to them. As regarded the military hospitals, he thought their organisation had hardly kept pace with that of the civil hospitals, and by contrast looked bare and cheerless. He disapproved, too, of the present plan of admitting into hospital every man who was unable to perform his full duty; he thought it prejudicial to the moral qualities, both of the soldiers and their attendants; it tended "to make them hypochondriacal, and to engender the habit of going into hospital for trifles;" a system which, when campaigning, might be attended with serious inconvenience. Nurses and orderlies, too, having to deal with many such cases, were apt to become careless, and to lose that sense of responsibility which they ought to feel for every patient.

The question of field hospitals was then minutely gone into, the present system criticised, and its weak points, as they appeared to the lecturer, were pointed out. In discussing the *personnel* of a field hospital he recommended that the medical staff should be selected much on the same plan as that adopted in the metropolitan hospitals, physicians, surgeons, and pathologists, so that they might be ready for any and every emergency. He laid great stress on the importance of having the food for the sick and wounded well prepared, and hospital cooks, he said, ought to be specially trained so as to be able to turn to the greatest advantage whatever materials might be served out to them. There were many other points in the lecture to which we do not allude, because of the limited space at our disposal.

Sir Joseph Lister, Bart., will take the Chair at the Parkes Museum, on Thursday, March 27th, at 8 p.m., when Mr. Watson Cheyne will give a demonstration of all the principle types of Micro-Organisms. Tickets for admission can be obtained through members of the Museum.

The Paris Municipal Council have decided to erect a statue to Broca, in the neighbourhood of the École de Médecine.

It may be well again to remind the Fellows and Members of the Royal College of Surgeons of the meeting which is to be held on Monday next. Important changes in the Charters of the College are to be proposed, not the least being one which is to give Fellows the power of voting by proxy. Such a radical change in the laws of so conservative a body as the College Authorities have hitherto shown themselves, is a sign of an enlightened policy, and of liberal views, which augur well for the future prosperity of the College. It is needless to point out that such a change, if effected, may completely alter the character of the Council; and it is only fair to the intellectual capacity of the Fellows at large to predict that changes which result from a more general participation of the Fellows at large in the management of College affairs will be a gain, both to the profession and to the public. It is a matter for regret that these changes were not earlier conceded by the present Council, and before an association had been formed, whose object was largely to effect them. It now only remains for the Members to band together and secure for themselves that share in College management which their number and personal interests entitle them to expect.

We are glad to be able to state that at a meeting of the Association of Fellows of the Royal College of Surgeons, held at Birmingham yesterday, a resolution was passed to the effect that the officers of this Association be authorised to state, at the meeting at the College on the 24th instant, that the concessions announced by the Council include all the objects for which the Association has contended, and that it desires to recognise the readiness and grace with which the Council has granted them.

The programme of the forthcoming Tercentenary of the Edinburgh University has been issued, and it promises to be an affair of some bigness; 80 delegates will represent various British and foreign Universities, and seventeen of them will receive honorary degrees; 62 honorary degrees will be conferred on unofficial guests, of whom 232 have been invited. Medals will be struck to commemorate the occasion; there will be a dinner to which 1,000 will sit down, and a torch-light procession of students with 1,000 torches. The proceedings will open on Tuesday April 15th, with a reception by the Lord Provost; on Wednesday the 16th, the Medical Faculty will give a luncheon in the new buildings of the University; on Thursday the honorary degrees will be conferred, there will be a luncheon at the College of Physicians, and an afternoon reception by the Royal Medical Society, and the Tercentenary banquet in the evening; and on Friday the President and Fellows of the Royal College of Surgeons will give a breakfast, and the students will wind up the affair with their illuminated stampede. A list of the medical delegates, and the medical men on whom degrees will be conferred, is given in our news column.

The Medical Sickness, Annuity, and Life Assurance Society has decided to accept members contributing for sickness pay alone, without combination with an

annuity. But it is not their intention to undertake the payment for sickness in old age, and the insurance for sickness pay must always cease at the age of 65. A table has been drawn up, giving the amounts payable per quarter, at each year of life from 20 to 49, to insure in sickness, two, three and four guineas per week respectively. A practitioner insuring at 33, which, we may take it, is about the age when the fear of the results of illness begins to grow oppressive, would for quarterly payments of one pound, thirty shillings, and two pounds respectively, be able to make himself sure of two, three, or four guineas a week in sickness. We are not sure that this department of the society will not prove the most popular in the long run. There are many practitioners who have insured their lives in other societies, and who have expectations from living relatives, and they are thus comfortable in their minds as to what will happen when they die or grow old; but they have no such security as to what will happen if they fall ill. For practitioners so placed, the new development of the society affords exactly what they want—the feeling that if they break down, one weight will be removed from their minds.

No members of the medical staff, fortunately, were killed in the battle of last week, but two, viz., Surgeon Prendergast, of the Army Medical Department, and Surgeon H. E. F. Cross, of the Royal Navy, were seriously wounded. Mr. Prendergast was speared in the chest as he stayed behind to look after the wounded, and was with difficulty saved by two soldiers, and Mr. Cross was wounded in the forehead by a bullet. Both are happily doing well. Mr. Cross comes of a medical family well known in London, and is very popular with a large circle of friends.

Last week the mortality in the great English towns, excluding London, remained almost exactly what it was in the previous week, and in the great Scottish towns showed a distinct fall; but in London there was a notable rise—the death-rate which had been 19·3 and 21·3 in the two preceding weeks having gone up farther to 21·6. The most unsatisfactory thing about this increase is, that it was due to the greater fatality of zymotic diseases, but for which the death-rate would have been unusually low. Two weeks ago the zymotic deaths in London only numbered 179, and were 51 below the average; the week before last they numbered 215, and were still seven below the average; last week they numbered 261, and were 31 above the average. Two weeks ago the zymotic death-rate was 2·3 per 1,000; last week it was 3·4. This increase is due to a greater fatality on the part of small-pox, enteric fever, measles, and whooping-cough, especially the two latter. This is especially unfortunate, considering that Dr. Longstaff has just been congratulating us on our victories over infectious diseases, and in a more superstitious age would have put down as a retribution for boasting.

The excessive mortality from whooping-cough deserves earnest notice. It has shown a steady tendency to rise during the last quarter of a year, the deaths in thirteen successive weeks having been 42, 46, 68, 63, 69, 80, 85, 78, 83, 82, 74, 92, and 117. The last figure, that of the current return, is as much as 37 above the average. Some steps ought to be taken by the sanitary authorities to prevent this terrible waste of infant life, but it is probable that more good could be done by a united effort on the part of hospital out-patient physicians. No child with whooping-cough ought to be allowed to visit any out-patient department—in the first place, because of the obvious danger of infecting other children, and in the second place, because no medicine that the most scientific and adventurous therapeutist could prescribe can ever counterbalance the harm done by bringing a child with whooping-cough out-of-doors. The true remedy for the evil is one which we have advocated before now, the establishment of half-a-dozen small whooping-cough hospitals where children could be rigidly kept in a temperature like that of a southern health resort.

Baron Huddleston, in giving judgment in the case of Weldon *v.* Winslow, commented on "the astonishing and," as he thought, "shocking fact, that with an order and a statement signed by paupers, and two certificates signed by men whose only qualification need be the possession of diplomas, and the fact that they were not related to the keeper of the asylum to which a patient was to be sent, anybody might be shut up in a private asylum." It is difficult to see the relevancy of this comment. Mr. Weldon undertook to pay Dr. Winslow 400*l.* a year for taking care of Mrs. Weldon, and the presumption therefore is, that he was not a pauper. Furthermore, since private asylums are conducted on business principles, and their proprietors look for a profit from their business, it is somewhat unlikely that any proprietor would be found to take charge of a patient on the order of a pauper. The observation of the learned judge might be interpreted to mean that any irresponsible person, casually fixed upon—a pauper even—may sign the order. If this is the meaning that he intends to convey, the learned judge is in error, for the form of order prescribed by Act of Parliament (16 and 17 Vict. c. 97, Schedule F., No. 2), requires that the order shall set forth the "Degree of Relationship (if any) or other circumstance of connexion with the patient" of the person who signs the order. So much for the qualification required of the person who signs the order.

As to the qualification required by the persons who sign the certificates, it appears astonishing and shocking to the learned Baron, that the possession of diplomas is the only qualification necessary. It is difficult to understand what more the learned judge would have. Does he think that it is unsafe to entrust this onerous responsibility to every man in the possession of a diploma? Would he restrict it to those only who have special experience in insanity? Then, is not Dr. Winslow one of the very class to whom the duty should be entrusted? Baron Huddleston may reassure himself. So long as medical men who sign certificates of lunacy are liable to be placed in the witness-box, and subjected to the ordeal that Dr. Winslow has just gone through, or so long as they are liable to the frightful

expenses of such an action as that of Nowell *v.* Williams, they are not likely to exhibit any undue eagerness to sign a document so fraught with danger to themselves.

At the meeting of the Paris Académie de Médecine, on the 11th instant, the election took place for supplying the place in the section of Medical Pathology, rendered vacant by the death of Prof. Lasègue. The section sent in its lists of candidates, arranged in the following order:—On the first line, M. Bouchard; on the second, M. Siridey; on the third, M. Damaschino; on the fourth, M. Cadet de Gassicourt; and on the fifth, M. Sanné. At a very full meeting of the members the order of precedence arranged by the section was not maintained, and M. Siridey received the support of 48 of the 85 voters present, and M. Bouchard 37.

The Medical Officer of Health for Croydon has reported to his Sanitary Committee the results of an inspection of "closets" in the district, from which he draws some important inferences. The number of closets inspected amounted to 8,275, all apparently belonging to the poorer class of houses. Of these 5,811 were "closets with water," and 2,464 "closets without water;" 1,339 of the latter being under fortnightly inspection, and the remaining 1,065 not regularly inspected. Some years ago, when Dr. Buchanan reported on the epidemic of enteric fever at Croydon, he specially recommended that all closets which were supplied directly from the main should have their water cut-off, as such method of supply was found to lead not only to waste of water, but to contamination of the water in the mains. This recommendation was adopted by the authorities, and as each water-closet was deprived of its water (and so robbed of its right to its name) it was placed under regular inspection. But besides these there were found to be, as above-stated, 1,065 water-closets which, from defective or removed fittings, were water-closets only in name. Of these, happily, only 25 were situated inside the house to which they belonged, for 40 per cent. were found in a filthy state, and some are described as being in a disgustingly dirty condition. Of the closets without water, under regular inspection, three per cent. are found dirty at every fortnightly visit of the inspectors. On the other hand, of the 5,811 closets with water, only 3·4 per cent. were found with dirty pans when recently inspected. In the Lambeth water area, which is an out-lying part of the borough, somewhat similar results were obtained; of the closets without water, .52 per cent., and of those with water, 12 per cent., were dirty.

Commenting on these statistics, the Health Officer says that he is strongly of opinion that closets, without water, are distinctly unsanitary, and are calculated to affect injuriously the health of those living in the houses to which they are attached. "I do not deny," he writes, "that a water-closet can be as effectually flushed by the pouring of a quantity of water into the pan from a bucket as by any flow of water from a cistern. But hand-flushing involves extra trouble, and human nature being averse to trouble, the pan frequently goes unflushed after use, and soon becomes dirty. The essence of the water-carriage system is the immediate removal of excremental matter while in its early and least harmful state; dirty closet pans are in direct contravention of its first principles. Excremental filth in the neighbourhood of dwellings must always be considered as injurious to health, and we know that emanations from the sick in certain diseases, notably in enteric fever, have the power of conveying the disease to others. . . . It has been said that in Croydon no illness has ever been traced to these closets without water. But there is no evidence whatever on this point in our possession, either to support or refute this statement. We rightly condemn as unsanitary, many conditions which unfavourably affect the public health, to which, however, it would be difficult to trace any specific disease. In reiterating my opinion, that closets without water are unsanitary and likely to affect injuriously the public health, I beg most respectfully to urge on your Committee the necessity of taking steps, as soon as possible, to remedy the evil."

A correspondent sends us this:—"The wide spread fear of contagious germs and the appreciation of the value of antiseptics seems to be more intense on the Continent than with us, if I may judge from what I saw and heard last year when on my travels. For example, the chance of inhaling tuberculous bacteria has been met by a sanitary spittoon, and the fear of absorbing poisonous matters at the other end of the body by antiseptic closet paper, both for use and placing on the seat. The former I met with in Germany under the name of 'Cellulose Closetpapier mit Salicylsäure getränkt,' and the latter in France as 'Feuille hygiénique de la siége des water-closets avant de s'y asseoir garantit de tout contact malsain et dangereux.'"

The subject of jequirity ophthalmia, which has engaged the attention of ophthalmologists and others a great deal of late, receives a valuable contribution from Dr. Klein, in a paper published in the last number of the *Centralblatt für die Medicinischen Wissenschaften*. A theory was propounded in the course of last summer by Dr. Sattler, that this peculiar form of ophthalmia had its origin in a special bacillus or its spores, believed to be present in the jequirity infusion. Dr. Klein's experimental investigation of the question has led him to meet this theory with a direct contradiction. Taking all possible precautions to sterilise the infusions employed, and to render septic contamination impossible at any stage of his proceedings, he successively injected portions of sterilised infusion into a clear cultivation material (solution of peptone), and beneath the conjunctivæ of the rabbit. The former was preserved in the usual manner, at a given temperature, and after 24 hours showed no trace of turbidity or any evidence of the development of micro-organisms, whilst in the same lapse of time an intense ophthalmia was set up in the inoculated animals. After another 24 hours the microscope failed to detect any sign of a bacillus, either in the cultivation fluid or in the purulent discharges from the affected eyes, nor did

the pus so discharged appear to have any infective power whatever. From these experiments it becomes clear that the active principle of the freshly prepared infusion has the power of producing ophthalmia independently of the presence of any micro-organism, and that the preliminary boiling of the infusion, which has been observed to render it innocuous, must not be attributed to the destruction of the bacilli as suggested by Dr. Sattler, but rather to the alteration of the active principle of jequirity which thus loses its fermentative action.

We have received the first number of a publication brought out under the auspices of the Independent Medical Practitioners' Association, a body lately formed in Calcutta, to guard the interests of the independent practitioners in that city, and to endeavour to make their grievances better understood by those in authority. It is manifestly unjust that those in Government pay should be allowed to compete in private practice with those who are less favoured. If their pay is not sufficient, and we believe that it is not, by all means let them receive adequate remuneration. But, we think, that our readers will probably agree with us, that the formation of such an Association as the present is more than justified when they peruse the following list of posts which one Government servant was allowed to hold. The gentleman in question was a Surgeon-Major in the Indian Army; he was also First Surgeon to, and Lecturer in Surgery at, the Medical College Hospital, Examiner in the Calcutta University, Editor of the *Indian Medical Gazette*, Consulting Medical Officer to one or more Insurance Offices, and to a Railway Company, Health Officer for the Municipality of Calcutta, and finally a General Medical Practitioner.

The sixth and concluding report of Dr. Koch to the German Government, on the pathological relations of cholera, of which a translation appears in our present issue, is deserving of the closest study. With that confidence which experience alone can give, Dr. Koch now proclaims that the bacilli which he described in his former reports are undoubtedly the cause of cholera. That he has failed to produce the disease in animals by inoculation he makes no secret of, but this does not, in his opinion, invalidate the accuracy of his conclusions. The bacilli of enteric fever and leprosy have been generally accepted as the essential factors in the spread of their respective diseases, and yet those maladies have never as yet been transmitted to animals. The observation that these bacilli possess a much lower resisting power than most, if not all, of such organisms, is one that may, perhaps, explain why outbreaks of cholera are more under the control of thorough sanitary measures than are some kindred maladies, and the speedy way in which the bacilli succumb to the influence of acid solutions enables us to comprehend the comparative immunity with which persons in good health can attend upon cholera patients.

The amended Medical Bill passed through Committee in the House of Lords yesterday (Thursday) afternoon. A brief report of the speeches will be found in another column.

THE GULSTONIAN LECTURES.

A certain American humourist once grievously complained of the Poet of the Breakfast Table's uncontrollable *penchant* for saying the things he would like to have said himself. Something of the same injured feeling will, not unlikely, be present in the minds of many, when they read Dr. Clifford Allbutt's Gulstonian Lectures. Just as there were, according to their own account, Darwinians before Darwin, and differentiators of typhus and typhoid before Stewart and Jenner, so now probably there will be not a few to maintain that they have long given due weight to the nervous element in dyspepsia, and been fully impressed with the difference between hysterics and neurotics. It would be extravagant to credit Dr. Allbutt with a discovery equal to those we have mentioned, but his main contention has this element of most great discoveries, that once stated it immediately commends itself to many as being exactly what they have long felt, though they have not had sufficient imaginative force to openly formulate it. Much of the best work in medicine has been of this character. The clinical lecture on typhoid fever, for instance, which Sir W. Jenner published a year or two ago, was generally acknowledged to be one of the most valuable of his many contributions to medicine, and yet there was hardly a physician, with any extensive experience of the disease, who was not ready to declare that the lecture contained nothing that he did not previously know. The late Mr. Bagehot probably had something of this sort in his mind when he enunciated the apparent paradox, that a rigid adherence to commonplace is the best avenue to success. But the commonplace that has the most force in it, is that which no one feels to be commonplace until it is formulated by some one else.

If there is one subject on which every practitioner alike feels himself qualified to write, and to argue, it is that of dyspepsia. It is a complaint of universal extension, and, unlike many others, has no limits of race, class, or climate. Martyrs to it are found not only, as Dr. Allbutt says, at every street corner, but even where civilisation has not got so far as streets. In that fresh and delightful book, "The Story of an African Farm," the Boer equivalent for indigestion is given the first place in a glossary of not more than a score of words. Then, in addition to its being the complaint of half their patients, there are few practitioners whose own stomachs have had no history. And most of us hold the possibly erroneous notion, that we know more about, and can describe better, a contest in which we have ourselves taken part, than one of which we have been merely eye-witnesses. For these reasons Dr. Allbutt's lectures will no doubt receive much more attention, and will probably have a much more vital effect on the theory and practice of the profession, than lectures which take us into the more recondite byways of medical science.

It is impossible in the space of this article to touch upon more than one or two of the many interesting points raised by the Gulstonian lecturer, and first, as to the use of the word "dyspepsia." It has been long felt that the application of the term to so many varying conditions is unscientific, but it

seems to us equally, if not more, unscientific, to discard a convenient expression, only to replace it by terms which depend on hitherto unproved theories. Many of the terms of disease, still in common use, have no better right to their place than "dyspepsia." What are hemiplegia, and paraplegia, and aphasia, and facial palsy, and consumption, and croup, but examples of names of symptoms made to do nosological duty provisionally, until science is in a position to give a full and satisfactory account of the pathological conditions on which they depend. They will no doubt disappear, with dyspepsia, as we get truer views of what lies behind them; some indeed, like paraplegia, are already becoming obsolete. But it cumbers progress rather than helps it to prematurely discard well-known terms, for others which in their turn may have to be discarded, when the theory on which they rest has proved to be untrue. The question with regard to dyspepsia, is whether the time has yet arrived, when we can safely substitute for it a more scientific nomenclature. If every practitioner had Dr. Allbutt's clinical insight, we might perhaps answer the question in the affirmative. But the whole tendency of his lectures is to show how difficult it is to unravel any given case of dyspepsia, and no one can doubt that for the present the ordinary practitioner's more sensible course will be to retain the use of a provisional term, which prejudges nothing, rather than to label his cases with terms implying a theory, and a consequent treatment, which, in nine cases out of ten, may turn out to have been erroneous.

Dr. Allbutt's vivid picture of the neurotic subject deserves, like all faithful observations faithfully and impressively rendered into words, to live amongst the medical classics of the future—an honour granted only to an infinitesimal proportion of scientific literature. It is a picture rather of a section of the neurotic family, than of the whole class, a section, too, which, we are inclined to think, is more peculiar to the North of England, than to the South. We meet, indeed, in London with neurotics who tally so accurately with Dr. Allbutt's picture, that, just as with the characters depicted by Miss Austen, or George Eliot, we are almost driven to conclude that these very acquaintances of ours must have sat as models for the picture. On the other hand, however, we are familiar with other neurotics, who possess not even a family resemblance to Dr. Allbutt's typical specimen. The traits of functional nervous disease probably vary far more with race and climate, than those of any other form of morbid deviation from health. Dr. Allbutt himself admits that the hystero-epileptic type, which is common in the Paris hospitals, and which has left its mark on the religious history of the Continent, is extremely rare in the North, rarer probably than it is in London; and it is quite likely that the type which Dr. Allbutt has found so common in his practice, would be regarded as anomalous by Professor Charcot. We doubt, indeed, whether the neurotic disposition can be so clearly differentiated from the hysteric, as the Gulstonian lecturer would have us believe, and we further doubt, whether the liability to neurosis is altogether a matter of individual temperament. No one, be his original contribution what it may, is entirely out of danger of becoming neurotic, if by any chance his "balance of nutrition falls below the needs of his expenditure." There are, no doubt, many human "engines with a light fly-wheel, and a small furnace," whose work is habitually fitful and unsafe. But a week's want of sleep, overwork, and impaired assimilation, will bring down upon the most steady-going nervous system the sufferings and want of control which habitually distinguish the so-called neurotic. In spite of these qualifications, we think that Dr. Allbutt has conferred an important boon on medical science, by placing before his profession, in such a masterly style, an aspect of disease which has hitherto been far too generally overlooked.

We must leave the consideration of many other interesting points raised in the Gulstonian lectures, until time has been given for their more measured consideration. It would be doing an injustice to Dr. Allbutt to treat the harvest of years of work on his part without giving full time for its assimilation. But we cannot leave the subject without a few remarks upon what will doubtless be seized upon as the most pregnant sentences in his lectures—those in which he arraigns a certain school of gynæcologists, who have not been unsuccessful, as the world estimates success. It is to his credit that he should have had the courage to speak out, with all the force derived from his position, what has hitherto been hinted at only darkly. There will be few members of the profession who will be inclined to find much fault with what he has said, for the reaction against the mechanical school of gynæcology is in full swing, and the specialty is now being taken up by men of larger calibre, than many who have hitherto made their names and fortunes by it. Our only regret is that his arrows were not winged with more sober-coloured feathers. There was weighty truth in what he said, but its weight would have been more felt if the glitter of his words had been less brilliant. Our contemporary, who is always so painfully anxious to screen the smallest member of the profession from attack, has indeed found its Nemesis, in being made the exponent of a measured and deliberate crusade against a whole phalanx of its readers.

DISLOCATED SEASONS.

The phenomenal, if grateful, weather of the past week calls attention anew to the modern vagaries of Nature. In few matters indeed does she show her abhorrence of hard-and-fast lines more, than in the gradual merging of those epochs which the world has been wont to recognise under the title of the Four Seasons. And yet, in temperate climes at all events, we have been accustomed to regard their several characteristic qualities as sufficiently typical and distinctive. The time is not long past when the mention of summer recalled the notions of hayfields and sunshine as appropriately and as certainly as that of winter was attended with the idea of hard roads and skating. Lately we have changed all that, and men are beginning to ask themselves, in these days of reconstructive legislation, how long it will be before a Royal Commission is appointed for the revision of the calendar and the readjustment of the seasons. It is, however, only too probable that

people can no more be cured of bronchitis, than they can be made virtuous, by Act of Parliament; nor is this necessary, since private enterprise is so far equal to the occasion as to commend the invalid to leave England in February, and to return "not with the swallows but with the harvest," although he is permitted to consult his almanac in order to learn which is the season nominally to be credited with holding sway. It is not, indeed, that we have had to chronicle a transposition of winter and summer, autumn and spring, during the last few years: a complete *bouleversement*, attended though it would have been with numberless inconveniences in the first instance, would have produced less practically unpleasant results, than those which ensue from that too impartial mingling of all the seasons which has given to each some of the discomforts of all, and the special good qualities of none. The marked and punctual contrasts, sometimes trying but yet useful, have been lost in a neutral uniformity, or degraded into irregular, haphazard freaks of variability, too sudden to be guarded against, too short-lived to be salutary. Such a state of things may be of comparatively little moment to those who have the means and leisure to seek abroad the climatic conditions which are most agreeable or most necessary to them, and for whom the ease and rapidity of modern travelling have robbed expatriation of its old-time terrors. It is otherwise with the great majority of those healthy folk upon whom fate has imposed a stay-at-home existence. To such, this blending of the seasons involves the positive loss of a combined rest and stimulus to which they have been so long habituated that its value is only appreciated when the effects of its withdrawal become manifest.

The regular and orderly succession of typical spring, summer, autumn and winter brings to those who cannot travel a very fair equivalent for a series of changes of climates, resting and recruiting mind and body by calling into special activity different factors of the physical and mental being. Whatever more subtle influences it may possess, one most important attribute of sunlight is its power of stimulating tissue-change. Chlorophyll, for instance, will develop in the leaf-cells of the young plant under certain conditions of temperature independently of the presence of light; but the action of the latter is requisite for the due performance of those processes of absorption, digestion, assimilation, and secretion, which collectively make a healthy growth and development. Similarly, in man, under the influence of abundant sunshine, tissue-change is rapid and energetic; but when sunlight is combined with genial warmth, as in "old-fashioned summer weather," this increased metabolism can be advantageously sustained, even with a food-supply less abundant than ordinary, because the organism is at the same time less heavily taxed for heat-production. Thus while certain functions are stimulated to special activity, comparative rest is secured for others, and a moderate amount of exercise is sufficient to ensure the excretion of the products of retrograde metamorphosis. On the other hand, during bright cold winter weather an increased food-consumption is needed to make good the loss of heat; this involves the necessity of increased excretion of effete and used-up material; and this, again, is favoured by the greater and more vigorous exercise to which a healthy person is stimulated by such weather conditions. Under these circumstances the healthy body secures, and is itself favourably reacted upon by, the healthy mind. But a dull wet summer robs life not only of much of its enjoyment, but of much of its energy besides; and the man who, in winter time, wakes morning after morning to bathe in the same thick fog, or to view the same leaden sky, to hear the same steady falling of the rain-drops, and to trudge through the same muggy atmosphere over the same mud-covered pavements, must take up the day's burden less cheerily than he who wakens to breathe a clean crisp air under a clear sky, and for whom Nature has decked the world with frosted silver, or has robed it in the purest and softest of white garments. Moreover, it should be remembered that, under the conditions which we are recalling, the special characteristics of one season are not suddenly succeeded by those of another, but that each merges gradually into the next, so that the trying juxtaposition of extremes is avoided by that imperceptible transition whereby usage becomes an equivalent of second nature.

By the invalid, indeed, more equable conditions of season and temperature are commonly preferred; yet this is a state of things fraught with drawbacks and dangers of its own—especially when continuous "mild" weather is at the same time accompanied with an absence of direct sunlight—and it has a tendency to bring even the strong and healthy to the verge of invalidism. The comparative immunity secured by a mild warm winter, permitting the relaxation of those precautions which the patient has been accustomed to observe at that time of the year, is sometimes dearly purchased by the advent of "the severest March for nearly forty years,"[1] and by "summer months" unusually remarkable for variable temperatures, unseasonable coldness, and dearth of sunshine. Nor must we forget that, after all, the invalids are vastly outnumbered by the comparatively healthy, to whom this jumble of the seasons' characteristics is positively deleterious. Throughout the last autumn and winter, diphtheria and allied forms of infectious sore throat whooping-cough, and other contagious maladies, were unusually prevalent, widespread, and continuous; in other words, certain diseases which we are daily coming more certainly to regard as dependent on the action of specific organisms, flourished persistently under conditions of moisture and temperature, &c., such as might be expected to favour the propagation and development of disease-germs; while, at the same time, their victims were rendered susceptible by the same enervating climatic conditions. A long continuance of mild weather will unbrace and make even the vigorous "tender," just as the hardy plant may be made unnaturally susceptible to sudden frost by subjecting it to hot-house culture: amongst those who live normally at or just below the line of health, instead of above it—in whom, to quote Dr. Clifford Allbutt, the balance of nutrition has fallen below the needs of expenditure—the effect of such treatment is, of course, more marked and

[1] "The Weather of 1883, as observed in the Neighbourhood of London," by Edward Mawley, Member of the Council of the Royal Meteorological Society, &c.

more easily produced. The winter of 1883–4 may, indeed, be termed a democratic one, in that it has suited the pockets, and has seemed to suit the health, of the great mass of the population—keeping work open for the out-door artisan for instance, and taxing him less heavily for fire and clothing. But it has not proved an unmixed good. There are few things more suggestive in Mr. Mawley's report than the statement that the January and February of last year were remarkably mild and remarkably healthy ; but that, with the onset of severe weather (in March), the death-rate rose with a bound, and continued much above the average throughout the two succeeding months. Reading between the lines, we might say that in March and April many people paid a heavy penalty for previous indulgence in unseasonable and debilitating weather. Nature holds her balance very evenly, on the whole : warmth and primroses at Christmas may have their equivalent in respirators and pneumonia in May ; and a frostless winter will, in its way, prove as harmful as a sunless summer.

CLINICAL PAPERS.

No. VIII.—Electro-Diagnosis.

It must be admitted that medicine, as an art, has, since the beginning of its history, made singularly slow and imperfect progress in the direct cure of disease, and at the present time we are almost as helpless in the presence of a serious organic malady as our ancestors found themselves to be. It must also, however, be conceded that medicine, as a science, has, especially of late generations, made vast and important advances, and by thus augmenting our knowledge of morbid conditions has thereby indirectly ameliorated human suffering and increased the longevity of the community. Not only has our information concerning the nature of living bodies and their abnormalities been extended, but our means of detecting and differentiating various disorders have been greatly perfected. This improved art of diagnosis, although doubtless in part due to the general diffusion of knowledge, is mainly the result of the success which has attended the introduction of physical agents as a means of research. In this way acoustics, optics, mechanics, chemistry, and a host of kindred sciences have been utilised in the elucidation of purely medical problems, and the stethoscope, the ophthalmoscope, the thermometer, and many other instruments might be cited as successful illustrations of the valuable results of this procedure. By this means the condition of the chest, throat, eye, uterus, and other internal organs have been explored, and their diseases physically demonstrated, and this ocular proof constitutes a means not only of displaying their existence, but of recording them with accuracy. The employment of such methods of investigation has given precision and exactitude to a profession which was formerly uncertain and indefinite, and therefore the prey of the mystic and charlatan, and has been mainly instrumental in removing the calling of medicine from their influence, and raising it as far as possible to the level of the exact sciences.

Until comparatively recent times, there was one class of disorder which more particularly baffled all efforts in this direction, namely, diseases of the nervous system. These on account of the delicate and complicated structures and organs involved, are especially difficult to study, and give few opportunities for the succesful employment of physical agents in their investigation. Electricity has now been proved to be a potent force for this purpose, and of late years information on the subject has been greatly developed and practically applied. Unfortunately, among the general members of the profession, a knowledge of its advantages has not yet been fully understood, and, like all other innovations, its utility has been even under-valued or decried. By those, however, who appreciate the extreme difficulty in the diagnosis of many obscure nervous affections, any means which will assist in the solution of the problem, will be received with respect. That electricity suitably applied by the initiated expert fulfils this object, is not now denied by the educated neurologist, although others still continue to doubt its utility. When the stethoscope was first introduced into practice, those who were ignorant of its advantages, or incapable of practically using it, denounced the instrument as worthless, and even asserted its revelations to be fallacious. Electricity at present occupies a somewhat similar position in medical practice, and its popularity is further diminished by the complexity of the diseases for which it is applied, the expensive and complicated apparatus necessary, and the skill and manual dexterity essential for arriving at successful conclusions.

It is not proposed in this short article to enter into the manipulative, or other details connected with electro-diagnosis, which must be sought for in the text-books on the subject ; it is only possible to briefly discuss the general objects to be looked for, and the results which have been obtained. Electricity in its different forms exercises a special and peculiar influence on all the various tissues of the body, but in the diagnosis of nervous diseases we practically limit ourselves to the effects of faradism and galvanism upon the motor nerves and muscles. In health, these agents have definite and well defined actions on the two structures in question, which are readily elucidated in the human subject by the adoption of suitable procedures. In disease these are modified and altered, and it is by utilising the relations which thus exist between the two conditions that important diagnostic information is gained. The *Faradic* current, when applied to the trunk of a motor nerve, causes a tetanic spasm of all the muscles it supplies, and this remains while it continues to flow. The same takes place when a muscle is stimulated, due to the effect of the current on the intra-muscular nerves. If the nervous supply is destroyed, as in curara poisoning, this form of battery induces no contractions, showing that faradism acts on the nerves only, and through them on the muscles, and not on the muscular substance itself. The *galvanic* current also causes muscular contractions when it is applied to the nerve trunks or their terminations in the muscle, but in a totally different manner from faradism, though still according to definite fixed laws. In addition, when the entire nervous supply is destroyed, this form of current has the power of acting

on the healthy muscular fibre itself, causing its substance to contract. This takes place independent of nervous influence, and is subject also to well defined rules.

In disease, all these conditions are modified or altered. If either nerve or muscle is in a morbid condition, these characteristic reactions are changed, and, in proportion, we are enabled to estimate their tissue deterioration. Such alterations are not only of degree, or quantitative, but of kind, or qualitative, and a consideration of their nature and relations furnishes accurate data upon which to depend in diagnosis, as from the condition of the electrical reactions the anatomical state of the nerves and muscles can be inferred. This general principle having been established, the practical results flowing from its application will be obvious. In all diseases of these two important structures, direct knowledge of a definite and accurate nature is obtained both for diagnosis and prognosis, for it has been further ascertained that a precise acquaintance with the histological state of the tissues, combined with the other circumstances of the case, enables us to successfully hazard a speculation as to their probable future progress. By means of electrical tests, lesions of nerve and muscle may be discovered, their extent determined, their nature ascertained, and their course foretold. In this way, also, they may be differentiated from the many other morbid conditions, which, in practice, may readily be confounded with them. For example, in the case of weakness of a limb of doubtful origin, how difficult it frequently is to determine the pathology of the disorder! Is it an affection of the nerves, muscles, bones, or joints; is it a strain or sprain; is it rheumatism, gout, or other constitutional disorder; is it a functional neurosis; is it of spinal or central origin? On many such perplexing positions, the definite and objective revelations of electrical investigation throw a flood of light, its positive indications giving direct information, and its negative results being in themselves highly suggestive.

In addition to primary degeneration of the nerves and muscles, it has been further determined that electricity comes to our aid in the detection of certain diseases of the nervous centres. It is now generally believed that in the anterior cornua of the spinal cord, there exist those elements which preside over the nutrition of the nerves and muscles, and these are so far independent of one another, that either may be separately affected. Whatever theory is adopted to account for the phenomena, the fact remains, that in certain degenerations of this tract both nerve and muscle are disorganised, and in others, only one of them is involved; in each case the disease presenting well recognised and distinctive clinical features, running a special course, having a peculiar distribution, and characteristic termination. Among the first is the so-called polio-myelitis anterior, or infantile paralysis, in which both nerve and muscle are degenerated; and among the second is progressive muscular atrophy, in which the latter only is involved, leaving the former intact. It is therefore apparent that an electrical investigation of such cases of cord disease must give valuable aid in their diagnosis, and determine with exactitude, and in a manner unattainable by other means, their extent and distribution, their distinction from one another, and from diseases of other organs. Again, in sclerosis of the posterior cornua of the cord, of its lateral and posterior columns, and other tracts, the nutrition of the nerves and muscles always remains intact, and consequently the electrical reactions are normal, which negative signs in themselves constitute a reliable means of differentiating between this affection and diseases of the anterior cornua.

Finally, in all forms of paralysis of cerebral origin, and those due to functional disorder, the electrical conditions remain unchanged, which in doubtful cases serves to distinguish between them and those resulting from lesions of the anterior cornua of the cord, or of the peripheral nerves, or muscles. Further reflection on the subject will also indicate that even in those diseases where the abnormal electrical reactions are similar in kind, they vary in distribution; the discovery and demonstration of which may be the means of determining the nature of the disorder, whether peripheral or central, the organ affected, etc.

From this very brief general sketch, suggestive of some of the more important objects to be obtained by electricity as a diagnostic agent, the various directions in which it can be utilised may be realised, as well as the necessity for cultivating an art so important in the determination of so complex a series of diseases as those of the nervous system. It is not, however, every one who can successfully carry out such an enquiry, as it demands technical knowledge, and special manipulative dexterity. Imperfect methods of application, the old-fashioned and utterly useless procedure of roughly dabbing sponges over the skin without order or system, have led not only to erroneous conclusions, but, in consequence, to distrust of the agent employed, and neglect of a really valuable method of physical research. Although the subject is admittedly a complicated one, and has not yet been fully developed, the difficulties connected with its appliances, like most others, can be overcome by practice and study, and doubtless as our knowledge extends, and the importance of the question becomes more fully recognised, further means will be arrived at to facilitate the procedure. In conclusion, although the employment of electricity in diagnosis is strongly advocated, we must guard against a too exclusive dependence being placed on its virtues, as it is unreasonable and unscientific to anticipate everything from its revelations. Like all other methods of research, such as percussion, auscultation, thermometry, etc., it must be remembered that it is only the means towards an end, namely, that of discovering, demonstrating, and recording actual positive states; like them, it is not to be exclusively employed, but must be looked upon as an adjunct only to all the other means of enquiry with which we attack the problem to be solved. All the circumstances of a clinical case should be investigated without omission of any, and every means in our power, including electricity, should be brought to bear on its elucidation. This last, if it is only one of the aids we employ, will, in conjunction with other facts and observations, prove a most valuable auxiliary in the hands of the physician for the detection of disease. Δ.

REVIEWS AND NOTICES OF BOOKS.

Descriptive Catalogue of the Pathological Specimens in the Museum of the Royal College of Surgeons of England. Second Edition. By Sir James Paget, Bart. Vol. II. London: J. and A. Churchill, 1883.—This volume is almost entirely occupied with the sections of diseases of bones and joints, including of course the injuries to these; no less than 490 out of the 526 pages being thus occupied. The other subjects that come in for a share of consideration are of comparatively minor interest; they are morbid conditions of the blood, injuries and diseases of voluntary muscles, injuries and diseases of tendons and sheaths of tendons, diseases of bursæ and synovial ganglia, and injuries and diseases of cartilage; these are exemplified by just 100 specimens, whilst the bones and joints require for their due display no less than 1,450 preparations. The extraordinary wealth of the College in this department ceases to suprise us, when we remember that the bones and joints are *par excellence* the hunting-ground of the younger branch of our art, and that in the exercise of their craft, they are much more likely to become possessed of pathological "curios," than the physician who can obtain such rewards only when his efforts have been crowned with failure. It will be interesting for those of us who are still to the front, when another edition shall be called for, to notice how some diseases have died out and others sprung up to take their place. The old fashioned syphilitic ulceration of bone, of which there are 40 preparations is, we believe and hope, of the former class; whilst in the latter we would place such diseases as osteitis deformans, to which disease only the three specimens from Sir James Paget's well-known case, read before the Royal Medical and Chirurgical Society, are at present attributed. The exact place which the bones, now grouped under the head of infantile syphilis, will then occupy, is a little doubtful; some of M. Parrot's specimens, however, will not be able to maintain their right to be classed apart from rickets; and, indeed, from his point of view, they would not be. As of the first volume so we may say of this, that it has been brought out in a way worthy of the great Institution it emanates from, and worthy of the distinguished surgeon and able assistants who have undertaken the editorial management.

Surgical Experiences of the Zulu and Transvaal Wars; by D. Blair Brown, F.R.C.S. Edinburgh. Oliver and Boyd, Edinburgh.—This book is a reprint of some papers which originally appeared in the *Edinburgh Medical Journal*, and which we gladly welcome in their now more accessible form. English surgeons, for very many years past, have had but little opportunity of adding much to the literature of gun-shot and other wounds sustained in war, owing to the time which has elapsed since our own army was in the field. It is therefore satisfactory to find that Dr. Brown has been led to publish his experiences. There are some points on which we shall have to join issue: thus, in the "general remarks on gun-shot wounds," he states that after injury with the modern rifle bullet, he has "seen so many instances of the healing process take place without any aid, after complete perforation of a thigh or arm," that he looks "upon the fact of a sloughing occurring as unusual." An extensive acquaintance with modern bullet wounds (in the Franco-German campaign) leads us to an exactly opposite conclusion. In another point our experience does not quite coincide with the author's: he says "when the shaft of a long bone is struck by a round bullet, long fissures and splitting up into fragments do not occur in the way they do when a conoidal one has hit a like bone." The shape of the bullet has little or nothing to do with the amount of splintering: this depends on the rate at which the bullet is travelling. A bullet which strikes a bone at a low rate of velocity, whether round or conoidal, shivers the bone; while, if travelling at a high rate of velocity, it may penetrate even without any splintering at all, as witness the many cases of "Lochschüsse" which occurred in the Franco-German war. It is on the same principle that a bullet may pass through a sheet of glass without splintering it; or it may not pass through it, yet shiver it into fragments. Again, in discussing the "necessary treatment to be adopted," whether "expectant," "conservative," or "operative," he says "here, indeed, the whole specialty of army surgery comes in. Any one can lop off a leg or an arm: the schools teem with second year's students who can do this: but the thing which ought to distinguish the 'army' from the 'ordinary' surgeon, is the knowledge of what injuries should be treated according to either of the above plans." Where can Dr. Brown have gathered this impression of civil surgeons? Are they not called upon to decide questions of this kind infinitely more frequently than their military brethren? How few of the latter have any practical experience of gun-shot wounds when they first join the army, and how few ever see anything of field service at all! These "general remarks" we think, are themselves a proof of a very narrow acquaintance with gun-shot wounds on a large scale, and we fear they would not be endorsed by any surgeon of experience. "Probably no better air and climate exist than that of South Africa." We agree with our author, and we fancy that his experience and ours differ chiefly because his wounded enjoyed these paramount advantages which ours did not. We only hope that he will not be misled, and attribute his successes to the wrong source. The details of the cases themselves are interesting and instructive; they form the most useful part of the essay.

The Essentials of Pathology; by Tod Gilliam, M.D., Professor of Physiology, Starling Medical College. H. Kimpton, London.—There are now so many small works on pathology that we are at a loss to understand why the elements of this branch of medical science could not be allowed to rest undisturbed for a short time. But, we presume, on the principle that one cannot have too much of a good thing, the "Essentials of Pathology" is introduced to the profession in the hope of "kindling a thirst for pathological investigation." This fiery metaphor is, we are bound to say, not indicative of the general tenor of the work, which is characterised throughout by a greater grasp of the English language than is usually found in medical books of this stamp. The author is fairly well up to date with his facts, and states them in a plain and comprehensible manner, but we venture to offer the opinion that this small volume would be found more suitable to the nascent lecturer than to the student for whom it is intended. The arrangement of the subject-matter deviates somewhat from the usual plan, though this slight novelty is not unmeritorious, and the engravings are all very old friends. Although the reason for the existence of this book is a little obscure, we think that, as its facts seem to be correctly stated, and are laid down lucidly, it may be useful under certain circumstances.

On Bedside Urine Testing; by George Oliver, M.D. Second Edition. London: H. K. Lewis, 1884.—To make the examination of the urine at the patient's bedside not only possible but easy and accurate has been Dr. Oliver's aim in writing this little book. His test papers are now so well known that they need no praise from us. As the practical outcome of his experiments and experience, we gather that in testing for albumen, he prefers the ferrocyanide of potassium, though not the most delicate, because it does not precipitate the peptones; whilst for quantitative analysis, he recommends the potassio-mercuric iodide on account of its greater delicacy. The method of making this examination is very simple; having decided upon a certain degree of opacity as a standard, all the albumen is precipitated by means of the reagent in a given quantity of urine, the opacity of this is then compared with that of the standard, and diluted till it exactly corresponds, the opacity of the standard being of course known for each reagent. Dr. Oliver does not dispense with heat altogether in testing for albumen, and he uses the citric acid papers separately in preference to the compound papers. The indigo-carmine test papers are strongly recommended in testing for sugar, and they certainly have given in Dr. Oliver's hands excellent results. We commend this little book, and the methods of which it treats, to our readers' careful attention.

ABSTRACTS AND EXTRACTS.

THE SIXTH REPORT OF THE GERMAN CHOLERA COMMISSION.

By Dr. Koch.

The question whether the bacilli found in the bowel of cholera patients are parasites belonging exclusively to cholera, which was left undecided in my last report, can now be looked upon as settled.

At first, on account of the varying pathological appearances presented by the bowel in cholera, and on account of the large number of bacteria always found therein, it was extraordinarily difficult to discover the truth. In most cases death does not occur at the height of the cholera process, but in the reaction-period which follows immediately after, and in which such considerable changes take place in the bowel and its contents, that it is impossible from such cases alone to obtain a clear idea of the cholera process. It is not until one has had the opportunity of examining a number of uncomplicated cases, and of comparing with them cases recently attacked, that one can succeed in obtaining a true insight into the pathological relations of cholera. For this reason it was thought right to exercise the greatest caution in interpreting the discoveries made with regard to bacteria in cholera, and to reserve a definite judgment on their causal relation to the disease until we had fully made up our minds on the subject.

In the last report I was able to state that peculiar characters had been found in the bacilli tenanting the cholera bowel, by which they could be distinguished with certainty from other bacteria. Of these features the following are the most characteristic :—The bacilli are not quite like a straight line as other bacilli, but a little curved, like a comma. This curving may even be so marked that the bacilli assume almost a semi-circular outline. In pure cultivations these curved bacilli often give rise to S-shaped forms, and to wavy lines of varying length, the former of which correspond to two individuals, and the latter to a considerable number of the cholera bacilli, which have remained in connection as they continued to proliferate. They possess, moreover, movements which are very active, and may be best observed in a drop of the cultivation solution suspended from a covering glass. In such a case one sees the bacilli swim across the field of the microscope with great rapidity in all directions.

Their behaviour on gelatine is peculiarly characteristic. They form colourless colonies which, at first, look as if they were composed of tiny glittering fragments of glass. Gradually these colonies cause the gelatine to melt, and then spread themselves out to a moderate extent. In gelatine cultivations, therefore, this peculiar appearance enables one to distinguish them from other colonies of bacteria with great certainty, and to isolate them from the latter with ease. They can, moreover, be demonstrated with comparative certainty by cultivation on concave slides, as they always betake themselves to the margin of the drop of cultivation liquid, and can there be recognised by their peculiar movements, and, after staining with aniline, by their comma-like shape.

So far twenty-two cholera cadavers and seventeen cholera patients have come under examination in Calcutta. All these cases were examined for the presence of the specific bacteria, both by the help of gelatine cultivations and also by microscopical preparations, and, in most cases, by cultivation on concave slides; the comma-like bacilli were found in all, without an exception.

This result, taken together with that obtained in Egypt, justifies the conclusion that this kind of bacterium uniformly occurs in the cholera bowel.

With the view of controlling the result, there were examined in exactly the same manner 28 other cadavers (including eleven dead from dysentery), and also the evacuations of a case of simple diarrhœa, of dysentery, and of a healthy patient who had recovered from cholera, besides various animals, both healthy ones and others which had died of ulceration of the bowel and pneumonia; and lastly, we also examined water, contaminated with putrid masses. In not a single case, however, did we succeed in demonstrating the cholera bacilli, either in the stomach or bowel of the cadavers, or in the evacuations, or in the other fluids, rich as they were in bacteria. As a disease process very similar to cholera is produced by poisoning with arsenic, an animal, so poisoned, was examined to see if the comma-bacilli were present in the digestive organs, but in this case also the result was negative.

From these results the further conclusion may be drawn, that the comma-like bacilli are altogether peculiar to cholera.

As to the relation of these bacteria to cholera, I have already explained, in a previous report, that either this specific kind of bacterium is specially favoured in its growth by the cholera process, and hence combined in such a striking way with cholera; or that the bacteria are the cause of cholera, and the disease only arises when these specific organisms have found their way into the bowel. The first hypothesis cannot be accepted, for the following reasons :—It must be assumed that a man when he sickens with cholera has already this kind of bacterium in his alimentary canal, and further, inasmuch as these peculiar bacteria were found without exception in a comparatively large number of cases both in Egypt and in India, two widely separated countries, it follows that every man must be tenanted by them. This, however, cannot be the case, for, as already stated, the comma-like bacilli have never been found except in cases of cholera.

Even in bowel affections, such as dysentery and enteric catarrh, which so often pass on into cholera, they were absent. It is also to be remarked, that, if these bacteria had been so regularly present in human bodies, they certainly would have been previously observed at some time or other, which is not the case.

As, therefore, the growth of these bacteria in the bowel cannot be produced by cholera, there remains only the second hypothesis, that they are the cause of cholera. That this is indeed the case, a number of other facts attest in an unmistakable manner; above all, their behaviour during the disease process. They confine themselves to the organ which is the seat of the disease, the bowel. In vomit they have only been twice recognised, and in both cases both the appearance and the alkaline reaction of the vomited fluid have proved that bowel contents, and with them the bacteria, have obtained access to the stomach. In the bowel itself they conduct themselves as follows :—In the first evacuations of patients, and as long as these retain their fæcal character, only very few cholera bacilli are found; the subsequent watery inodorous evacuations, however, contain them in great numbers, all the other forms of bacteria almost completely disappearing from that moment, so that at this stage of the disease, the cholera bacilli form in the bowel almost a pure cultivation. As soon, however, as the attack of cholera subsides and the evacuations again become fæcal, the comma-like bacteria gradually disappear from the evacuations, and when the disease has completely passed over, are no more to be found. What is found in cholera cadavers is exactly similar. No cholera bacilli are met with in the stomach. The bowel contains them in varying numbers, according as death has occurred during the cholera attack, or after it. In the most recent cases—in which the bowel presents a uniform bright red colour, the mucous membrane is still free from extravasations of blood, and the contents of the bowel consist of a whitish inodorous fluid—the cholera bacilli are found in the bowel in enormous quantities, and almost pure. Their distribution corresponds

quite accurately to the degree and extension of the inflammatory irritation of the mucous membrane, while in the upper part of the bowel they are not usually so numerous, but increase towards the lower portion of the small intestine. If, on the other hand, death occurs later on, we find the signs of a considerable reaction in the bowel. The mucous membrane is of a dark colour; in the lower part of the small intestine it is covered with blood extravasations, and its most superficial layers have often ulcerated away. The contents of the bowel are in this case more or less blood-stained, and in consequence of renewed development of putrefactive bacteria, are putrid in character and offensive. The cholera bacteria in this stage do not reappear in the contents of the bowel, but they are still present in considerable numbers for some time longer in the tubular glands, and often also in the neighbouring tissues, a fact to which attention was first called by the appearance of these peculiar bacteria in the bowel of the Egyptian cholera cases. They are entirely absent only in those cases which die from some sequela, when the cholera attack has quite passed off.

The cholera bacteria behave, then, exactly like all other pathogenic bacteria. They appear exclusively in their own peculiar illness, their first appearance coinciding with the commencement of the disease; they increase in number proportionally to the advance of the disease; and disappear with its decline. Their seat corresponds in like manner with the extension of the disease-process, and their number is, at the height of the disease, so considerable as to be quite sufficient to explain their destructive influence upon the mucous membrane of the bowel.

It would certainly be very desirable to succeed in producing in animals artificially, with these bacteria, a disease analogous to cholera, so that their causal relation to cholera might receive ocular demonstration. In this, however, we have not yet succeeded, and it is even questionable whether success will ever be attained in this direction, because, according to all appearance, animals are insusceptible of the cholera infection. If any species of animal whatever could take the cholera, it would surely have been observed in a reliable manner in Bengal, where the infective material of cholera is met with throughout the year and throughout the land. All enquiries, however, directed to this point have met with a negative result.

Nevertheless, the demonstrative force of the facts given above is not weakened by the failure of the experiments on animals. The same phenomenon meets us, also, in other infective diseases; for instance, in enteric fever and in leprosy, two diseases in which specific bacteria also occur, but which hitherto no one has succeeded in conveying to animals; and yet the mode of appearance of the bacteria in these diseases is such, that they must undoubtedly be regarded as the cause of the disease. The same is true also of the cholera bacteria.

Moreover, the further study of the cholera bacteria has enabled us to recognise several other characteristics which are all in harmony with what is known about the ætiology of cholera, and thus must be regarded as an additional confirmation of the correctness of the hypothesis that the bacilli are the cause of cholera.

The most remarkable circumstance relative to this, is the fact that it has been repeatedly observed that when the linen of cholera patients, after being soiled by their dejections, has been kept for 24 hours in a moist state, the cholera bacilli are found to have multiplied in a most extraordinary manner. This will account for the well-known fact, that the linen of cholera patients has so often infected those persons who have to do with it. Attention having been called to this observation, further experiments were made, and it was found that the same phenomenon occurred whenever cholera dejections, or the intestinal contents of cholera cadavers, were spread upon linen or blotting paper, kept moist, and especially upon the surface of damp soil. In 24 hours the thin film of mucus was invariably found to be completely converted into a thick mass of cholera bacilli.

Another very important quality of cholera bacteria is that they die off after drying more quickly than almost any other form of bacteria. As a rule, even after three hours' drying, every vestige of life has disappeared.

Another peculiarity is that they will only grow in alkaline cultivation-fluids, even a very small quantity of free acids, which would have no tangible effect on the growth of other bacteria, delaying their development in a striking manner.

In the healthy stomach they perish, which will account for the fact that over and over again it has been found impossible to detect them in the stomach or intestines of animals, which had been fed for a considerable period on cholera bacilli, and then killed. This last characteristic, together with their slight power of resisting drying, explains what daily experience teaches us, viz., that infection so seldom follows upon direct contact with cholera patients or their ejecta. Evidently other peculiar circumstances must be present, in order that the bacilli may be placed in a position to pass through the stomach, and then to produce the cholera processes in the bowel. Possibly, bacilli can pass uninjured through the stomach, when digestion is disturbed, a hypothesis supported by what is seen in all cholera epidemics, and uniformly noted here in India, viz., that those men are especially liable to cholera, who are suffering from indigestion. Perhaps, however, some special condition under which these bacteria may occur, and which would be analogous to the persistent condition (*Dauerzustand*) of other bacteria, may enable the cholera bacteria to pass the stomach uninjured.

It is not probable, it is true, that this change consists in the production of persistent spores, for such spores have been found to retain life for months and even years, whereas the cholera poison does not remain active longer than about three to four weeks. Nevertheless, it is quite conceivable, that some other form of persistent condition exists in which the bacilli can remain for some weeks alive in a dried state, and in which they are also in a position to resist the destructive influence of gastric digestion.

The conversion into such a state would then correspond to what Pettenkofer has described as the maturing of the infective matter of cholera. Hitherto we have not succeeded in discovering such a persistent state on the part of the cholera bacilli.

OPHTHALMOLOGY.

Blindness from Retinal Thrombosis after Facial Erysipelas.—A man, aged 40 years, who had had syphilis, underwent a severe attack of facial erysipelas. On the eighth day, the sight of the right eye was impaired, and on the following day that of the left. On the next day (the tenth) he was quite blind, and on this day Dr. Knapp ("Transactions of the American Ophthalmological Society," 1883) saw him for the first time. He found swelling of the lids, and chemosis, incisions had already been made for the relief of tension, the pupils were widely dilated, and there was no perception of light. The left fundus showed a milky retina, pervaded by numerous dark, almost black, tortuous vessels, overfilled, which tapering, converged to a common centre, and had upon, and between them, many irregular dark hæmorrhages. The character of all the vessels was the same, they appeared as enlarged veins. Two days later, the veins presented the same aspect, but some were thicker, and had elliptical intumescences. Between, and crossing them, were seen thin, straighter, and red vessels (arteries), with punctate, striated, and irregular bright red hæmorrhages, whereas the older ones were dark brown. A trace of the optic disc was visible, the yellow spot could not be made out, the periphery of the fundus was whitish-red, pervaded by dark blood-vessels, amongst which the arteries were not distinguishable. Ten days after this, it was noted that the vessels were thin on and near the disc, with white seams lining a thin red thread in the centre. Two months after the onset of the blindness, the patient was quite blind, the pupils were large and immovable, the discs were white, all the upper and most of the lateral vessels were converted into white streaks, varying in thickness along their course, some quite pervious, others interrupted by white segments, and there were numerous branches in the region of the yellow spot, all white. The points upon which Dr. Knapp lays most stress, are that the sequence of events was as follows:—Compression of the

central arteries of the retinæ producing blindness, followed by thrombosis of the retinal veins, then decrease of the swelling in the orbit, or the establishment of a collateral circulation, permitting the return of a limited flow of blood into the retinal arteries, which, however, being impeded by the blocked veins, led to renewed extravasations, to thrombosis and shrinking of the arteries, and finally to atrophy of the optic nerve. The changes were not the result of neuro-retinitis.

Regular Astigmatism.—The *New York Medical Journal* (January 5th, 1884), contains a useful paper, which was read by Dr. M. Landesberg before the Philadelphia County Medical Society. The author establishes the transitory character of certain instances of regular astigmatism; and states that "the conditions under which regular astigmatism may develope are—progressive myopia, with and without spasm of accommodation; spasm of accommodation in an emmetropic, myopic, or hyperopic eye." In his first communication on this subject, in von Gräfe's "Archiv für Ophthalmologie," xxvii., 2, he gave the history of fourteen cases which had come under treatment on account of progressive myopia and various asthenopic troubles. All were complicated with regular astigmatism, which varied in degree from 1-36 to 1-10. Treatment directed to the asthenopic disorders, or to the progressive myopia, not only cured the affection proper, but also entirely removed the astigmatism, which subsided *pari passu* with the decrease of the other morbid symptoms. He has since met with thirteen additional cases presenting similar characters and course. In some of these, the astigmatism had previously been treated with appropriate combinations of cylindrical and prismatic lenses, which acted, at first, "like a charm;" but the apparent good effect soon wore off, and the children were left in a worse plight than before. Treatment directed to the accommodation disorder cured all the troubles, including the dependent astigmatism. Three of these cases are related in detail.

Visual Area in the Brain.—To demonstrate, by the aid of pathology, that the centres for vision are seated in the occipital lobes is the aim and object of a paper by Dr. Allen Starr, in the January number of the *American Journal of Medical Sciences*. This he determined to do by a study of the recorded cases in which lateral homonymous hemianopsia was a symptom; other forms of hemianopsia are neglected, because they always relate to lesions of the optic commissure or one of the optic tracts. He has collected, in all, 32 cases, and it is needless to say that a post-mortem examination was made in each of them. An analysis of these leads him to the belief that lateral homonymous hemianopsia may result from lesions in the following situations, viz., in the optic tract, the pulvinar of the optic thalamus, the fibres of Wernicke, and the white matter or cortex of the occipital lobe. A lesion in the course of the optic fibres of one side, at any point between the optic chiasma and the cortex of the occipital lobe, produces partial blindness of both eyes. He, therefore, concludes that "the occipital lobe of each side is in anatomical and functional relation with both eyes in such a manner that the like-named sides of both retinæ are connected with the like-named hemisphere. When a lesion of one hemisphere involves the optic fibres at any point, partial blindness of both eyes, and not blindness of the opposite eye, is produced." He then proceeds to the consideration of the schemes which have hitherto been propounded on the subject, viz., Charcot's, Grasset's, and Ferrier's. Charcot's idea was, that those fibres which do not decussate in the optic commissure do so in the corpora quadrigemina; Dr. Starr rejects this, partly because there has never been any anatomical evidence in support of it, partly because there is good reason for doubting whether, as a matter of fact, crossed amblyopia ever does result from lesion of one hemisphere, and lastly, because Charcot himself has dropped it. Grasset's theory makes the fibres from the outer part of the retina decussate twice, once in the corpora quadrigemina, and once in the corpus callosum; this would explain the facts of hemianopsia, but it is a very complex arrangement, and as yet has no anatomical foundation. Ferrier placed the centre of vision in the angular gyrus; but Dr. Starr points out that lesion of the angular gyrus has been recorded without any impairment of vision, and he surmises that in the experiment on the angular gyrus, which Dr. Ferrier relied upon in support of his position, he must have damaged the fibres of Wernicke which pass immediately beneath it. The hemianopsia is always more marked in the eye on the side opposite to the lesion, and for this reason Dr. Starr thinks that cases of this class may often have been called crossed amblyopia. In all the cases included in this paper central vision was retained, and this agrees with the condition observed by Dr. Sharkey in a patient recently brought before the Ophthalmological Society, in whom with right homonymous hemianopsia there was a considerable area of normal central vision on all sides of the fixation point. Lateral hemianopsia is to be regarded as evidence of a local lesion in the opposite hemisphere; it gives us no clue to the nature of that lesion, nor can we without such associated symptoms as hemiplegia, hemianæsthesia, &c., form any opinion whether the lesion be in the occipital lobe, the fibres of Wernicke, or the pulvinar.

The Lateral Associated Movements of the Eyes.—The fact that the internal rectus of one eye acts with its fellow during convergence, and with the opposite external rectus during lateral movements of the eyes, long ago suggested that it had a double nervous supply. A good deal of light has been thrown on the subject of late by Duval, Graux, Laborde, Parinaud and others. In the *Liverpool Medico-Chirurgical Journal*, Nos. 5 and 6, Mr. G. A. Woods publishes a very thoughtful paper on the subject, in which he carefully reviews the anatomy and physiology of the sixth nerve, and analyses the symptoms in one series of cases where the nucleus of the sixth nerve was destroyed or damaged by disease, and another where the trunk of the nerve was so affected. His conclusions may be abridged as follows:—the sixth nerve appears in the human fœtus about the twelfth week, its apparent origin is from the groove which separates the anterior pyramidal body from the pons Varolii, it occasionally sends a small filament to the lenticular ganglion. It is essentially a motor nerve. If the nerve be divided between its apparent origin and termination, internal strabismus on the same side alone results. If the nucleus of origin be destroyed, there follows paralysis of the external rectus, with partial paralysis of the internal rectus of the other eye. Some of the fibres from the sixth nerve nucleus pass along the floor of the fourth ventricle, parallel with the raphe, to the third nerve nucleus, and then decussate and become incorporated with the third nerve on the opposite side.

Hysterical Amblyopia.—In a very interesting paper on thrombosis of the retinal artery, to which we have recently (p. 119) had occasion to allude, contributed to the *Ophthalmic Review* (January and February, 1884), by Mr. Priestley Smith, some light is thrown on this subject. The case which we have already commented upon, was, it will be remembered, one where a young woman had already lost the sight of one eye, and was threatened with blindness in the other, from deficiency of blood supply to the retina associated with disease of the ovaries, and Mr. Priestley Smith points out that the impairment of vision in this patient's non-blind eye, bore the closest resemblance to what is found in cases of hysterical amblyopia, or "neurasthenic amblyopia" to give it its full name. The physical signs of this condition may be said to be a contracted field of vision, venous congestion of the retina, and sometimes slight œdema of the disc, and Mr. Priestley Smith's contention is that this state is the expression of an impaired nutrition of the retina, not of a central disturbance.

OBSTETRICS.

Iodine Injections in Ovarian Cysts.—Prof. Cantieri, of the Medical Clinic at Siena, relates two cases of large ovarian cysts, which were completely cured by intra-cystic injections of tincture of iodine.—*Lo Sperimentale*, October.

REPORTS OF SOCIETIES.

THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY, MARCH 13TH, 1884.

JONATHAN HUTCHINSON, F.R.S., President, in the Chair.

Living and Card Specimens.

MR. R. M. GUNN exhibited a little girl, aged eleven years, in whose retina there could be seen a direct arterio-venous communication. She had come under observation for headaches, from which she had suffered for four years. On examining the left eye it was seen that a branch of the inferior temporal vein sent an offshoot which ran directly into the superior temporal artery. Several of the retinal veins appeared to commence abruptly, doubtless having their origin in the choroid, and piercing the retina vertically.

Dr. ORMEROD showed a man, aged 44 years, suffering from paresis of the upward movement of the eyes. It was most marked in the right eye, especially when the patient looked to the right. There was vertical nystagmus when he tried to look upwards. The other ocular movements were normal, no definite neuritis. The symptoms had been present ten months, but he had a similar condition fifteen years previously.

Mr. STREATFEILD showed a man, aged 22 years, the subject of inherited syphilis, who had had disease of the bones of his face since the age of fourteen years, which had led to an eversion of the lower lid on the left side, the cornea being clear when he came under observation. A raw surface having been made beneath the lid, Mr. Streatfeild transplanted a piece of skin from the forearm, using antiseptic precautions. The upper half of this piece of skin lived, and the deformity had been very much diminished by the operation.

Mr. G. E. WALKER showed a patient whom he had treated for sympathetic ophthalmia by removal of a portion of iris.

Mr. H. POWER, in reference to this case, observed that it was evidently one of those fortunate ones where the iris alone was involved, when this was not the case, mere removal of a piece of iris would not effect a cure.

Mr. ADAMS FROST exhibited a new artificial eye. The lens had a focus of 40 millimetres, and could be shortened or lengthened at pleasure. There were two retinæ, one of ground glass graduated in millimetres, and there were two clips in front to hold lenses. The other retina represented the normal fundus.

Mr. G. L. JOHNSON exhibited an Improved Trial Frame contrived to secure greater accuracy and perfection in adjusting spectacles and estimating refraction.

Mr. A. STANFORD MORTON showed a drawing of a case of hæmorrhage into the macula, and hoped to be able to exhibit the patient at the next meeting.

Mr. F. HODGES showed a girl, with an irregular granular-looking body on the outer sclera, which had first been noticed in the outer ciliary region, its formation being followed by iritis, hypopyon, and perforation of the sclera.

Mr. NETTLESHIP exhibited the following drawings:—(1) Central areolar choroidal atrophy. (2) Central senile guttate choroiditis (Tay's Caoroiditis). (3) Syphilitic retinitis, with retinal hæmorrhages, and growth of new blood vessels from the disc into the vitreous humour. (4) Glaucoma with retinal hæmorrhages, thickening of retinal veins and obliteration of arteries. (5) Nævus (?) lymphatic, affecting the brow, orbit and exterior of the eyeball, with lamellar cataract. No cataract in the other eye.

Mr. M. M. MCHARDY showed a man with a persistent hyaloid vessel in the right eye and choroido-retinal changes attributable to inherited syphilis.

Mr. GUSTAVUS HARTRIDGE showed a drawing of a case of tumour of the choroid.

Mr. COWELL showed a woman with a new growth (presumably sarcoma) in the region of the ciliary body.

Mr. ARTHUR H. BENSON (Dublin) exhibited the following ophthalmoscopic drawings:—(1) A case of monocular coloboma of the iris, lens and choroid with a bridge of iris-tissue over the coloboma. (2) Central choroiditis, monocular, pigmented. (3) Central choroiditis and retinitis binocular, slightly pigmented. (4) Choroido-retinitis, extensively pigmented. (5) Choroiditis (myopic) extensively pigmented. (6) Thrombosis (? embolism) of central artery of retina.

Retinal Glioma.

Mr. SIMEON SNELL (Sheffield) related two cases of retinal glioma in one of which shrinking of the eyeball occurred without perforation. (1) A child, aged eighteen months, had, when first seen, at the posterior part of both eyes, a yellowish deposit, most marked in the left. A history of fits was given, and of "congestion of the brain." The opinion formed at this time was strumous deposit. During the next three months the left globe became filled with deposit, the iris infiltrated and exudation appeared in the anterior chamber. The eye next began to soften and shrink, being ultimately reduced to a small stump. Soon afterwards the right eye, which had remained fairly quiescent, began to undergo similar changes, but the eye did not shrink, and a year after the onset was excised, the growth presenting the microscopical characters of glioma. The disease recurred in the orbit, and the child died six months later. The chief points of interest in the case were, whether the disease was from the first glioma—the shrinking of the first globe was very unusual, and against the idea of glioma. Possibly his original diagnosis of struma was correct, and the glioma had been engrafted upon an already damaged eye. (2) An infant, aged eight months, presented when first seen a whitish looking growth at the posterior part of each eye, this appearance had been noticed since the child was three months old. The right eye was removed, the growth appeared to be composed of caseous material. Three years later, the left eye, being quite filled by the growth, was removed. The child died eighteen months after with a tumour on her forehead. The points to which the author called attention were, that the disease was probable congenital in both eyes, that it remained quiescent in the left eye much longer than in the other, that there was no recurrence in either orbit but on the forehead, and this was attributed to a blow.

Dr. BRAILEY mentioned the case of a child whose right eye had been removed for a tumour which was found on microscopical examination to be an undoubted glioma, the left eye had been removed some years previously, having all the appearances of pseudo-glioma, and after excision he had examined it and found no evidence of glioma, though there was a connective tissue growth in the choroid. He thought it probable that there was some close connection between these two diseases.

Severe Conjunctivitis from Whisky thrown into the Eyes.

Mr. G. A. BROWN (Tredegar) communicated this case. The patient was seen the day after a glass of neat whisky had been thrown in his eyes. Both eyes were closed, lids much swollen with yellowish, sanious semi-purulent discharge. The lower half of each cornea was covered by a diphtheritic-like membrane, which peeled off, leaving the cornea clear. The conjunctivæ were deeply injected, and there were slight ecchymoses, but no chemosis. There was much pain and intolerance of light. Under belladonna fomentations, and syringing with a warm weak solution of boracic acid, improvement rapidly took place. In two days the membrane had disappeared, and the conjunctivitis and photophobia soon subsided, so that the man was well in a fortnight.

The Treatment of Glaucoma.

Mr. M. M. McHardy recommended an unusually large primary section for iridectomy in primary chronic glaucoma. He advised as large an incision as for a full-sized cataract; measured from the outside of the puncture to the outside of the counter-puncture in a straight line, it should equal the corneal diameter. The incision was parallel with, but one millimeter behind, the margin of the cornea. The size of the section did not appear to increase the frequency of malignant glaucoma, from an advance of the lens, a catastrophe which happened in one out of thirty cases, and was then happily relieved by the spontaneous escape of the lens, without any loss of vitreous humour, 22 hours after the operation. This eye made a favourable recovery, and subsequently exhibited a far more satisfactory degree of tension than the fellow eye which had been treated since by a maximum iridectomy, but from which the lens had not been removed. The patient was exhibited. In the case of a man with recurrent subacute glaucoma, upon the return of the glaucomatous symptoms, after a very free upward iridectomy, a similar iridectomy was practised downwards; the lens presenting in its capsule was ejected during the operation, and the case treated as after an extraction, the patient making an uninterrupted recovery. A patient who had undergone these operations was shown, his best eye seeing $\frac{6}{12}$.

Mr. G. E. Walker (Liverpool) showed a man, aged 57 years, on whom he had performed hyposcleral cyclotomy, for acute glaucoma. The patient was in great pain when first seen, and had merely perception of light. His operation was the exact opposite of Mr. McHardy's, for his incision was not more than one-sixteenth of an inch long. In this case keratitis had been set up by it. He had long held that all glaucoma was inflammatory, produced by inflammation of the ciliary body, and the modus curandi must, therefore, be by rest and relief of the ciliary body. The ultimate cause of glaucoma was excessive action of the ciliary body. After cyclotomy, the tension came down very slowly, in his patient it took several weeks. He thought that iridectomy must tend to close Schlemm's canal, rather than open it. If glaucoma was due to over-taxed accommodation, then, by attending to the refraction, we ought to be able to prevent it, as surely as we could prevent small-pox by vaccination.

Mr. McHardy had examined Mr. Walker's case, and did not consider it one of primary glaucoma at all, there were many synechiæ which could not have resulted from the glaucoma. Then, too, it was a case of acute, and not of chronic glaucoma, and his own observations had dealt only with the treatment of the chronic form, almost any operation would cure the acute form. If glaucoma was due to overwork of the ciliary muscle, why did it not commonly occur in students? Also, why should atropine aggravate and not relieve glaucoma on this hypothesis?

Mr. Walker, in reply, was satisfied that the iritis was clearly secondary in his patient.

Spasm of the Ocular Muscles.

Dr. Gowers made a short communication on this subject. He commenced by pointing out that in *chorea* the head and eyes might participate, the latter so irregularly that diplopia might result. His attention had been drawn to the subject by the case of a young woman who had headache, optic neuritis, double vision, and chorea. It was thought at the time that there was some gross organic disease, but she had completely recovered. Hence the diplopia must have been due to irregular spasm of the ocular muscles. Since this case he had been on the look-out for this symptom in chorea, and found it was not very uncommon. Next he took *partial convulsion of ocular muscles*. These participated almost uniformly in unilateral convulsion. He mentioned the case of a man, aged 36, who for six months had suffered from a hot rushing sensation in the inner canthus of the left eye at the commencement of his attacks; during them there was temporary loss of consciousness, the left eye moved outwards, and remained still at this time—once the pupil was noted to be dilated. He had many attacks daily, and his vision was reduced to one-fifth. In the case of a man, aged 47, there was occasional double vision; during the attack the left eye moved outwards, the right remaining still; there was blinking. The attacks recurred daily; they lasted a few seconds only, and at the close the left upper lid drooped for a minute. In a man, suffering from Bright's disease, he had seen *convulsive nystagmus*. Both eyes were deviated strongly to the left, from time to time still more so, and there was nystagmus quickly to the left. He died with symptoms of disease of the pons, and an anæmic area was found in the right half of the pons, just above the nucleus of the sixth nerve. That the conjugate deviation was not purely paralytic in all instances was evident from this case.

Ophthalmia Neonatorum.

Dr. David M'Keown (Belfast) made an important communication on the subject of the prevention of blindness from the purulent ophthalmia of infancy. After alluding to the very serious nature of the affection, he mentioned that on the Continent statistics had shown that at the blind asylums, 40 per cent. of the inmates were blind from this cause. He thought that steps ought to be taken to impress on the public the frequency and extreme importance of the affection, and the necessity for seeking medical advice whenever a child's eyes were affected. And he thought that the best way to put these ideas into practice would be through the agency of the poor-law organisations throughout the kingdom, and he asked the Society to pass some resolutions on the subject, and to take steps to bring the matter under the notice of the Government.

Mr. Tweedy, in rising to second the resolution, expressed the satisfaction he felt that such a resolution should have been proposed, and his regret that it had not been done long ago. All who were engaged in ophthalmic practice must see a number of cases of serious impairment of sight from purulent ophthalmia in infancy, not one of which would have lost their sight if properly treated in the early stage. When seen early enough, if the cornea was clear, the case should never be lost, and the same remark applied to diphtheritic ophthalmia. Wiser views were now prevailing amongst the community, and serious ophthalmia was less common than formerly.

The President observed that the subject was one of the greatest importance, and the Society were indebted to Dr. McKeown for bringing it forward. He had considered the matter very carefully, and he did not think that the passing of such resolutions came properly within the scope of the Society, he thought, therefore, it would be better that the subject should be referred to a committee.

Mr. Frederick Mason, after alluding to the great interest that the subject must always possess for those engaged in ophthalmic practice, moved that a committee be appointed to consider the whole subject, and report to a subsequent meeting.

Mr. Nettleship seconded the motion.

The following were nominated to act as a committee:—Mr. Mason; Dr. Fitzgerald, Dr. Argyll Robertson, Mr. Carter, Mr. Priestley Smith, Mr. Nettleship, Mr. Tweedy, Mr. Gunn, Dr. McKeown, and the President and Secretaries *ex officio*.

The Therapeutic Value of Jequirity.

Mr. Arthur Benson (Dublin) gave the results of a clinical investigation into the mode and manner of action

of jequirity. He had found that the ophthalmia could be produced by (1) the fresh powdered seeds; (2) the freshly made infusion; (3) the infusion after bacilli had grown in it; (4) the infusion six weeks old, and swarming with micro-organisms of most varied types; (5) the infusion after these bacilli had ceased all motion, and had sunk to the bottom of the liquid, apparently dead. He had examined at all stages of the disease the discharges and membranes from eyes affected with jequirity ophthalmia, without ever seeing the typical bacillus. The inoculations of the discharges and membranes were entirely devoid of infective qualities. He was thus able to confirm Dr. Klein's researches. Mr. Benson used the fresh infusion made from the seeds not decorticated, but passed through a coffee-mill. He had a high opinion of the value of the treatment in granular lids, and had never seen any serious injury result from its use. In one case, there was a short attack of iritis after each application, and in others some infiltration of the cornea occurred.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MARCH 18TH, 1884.

J. WHITAKER HULKE, Esq., F.R.S., President, in the Chair.

Congenital Absence of the Femora.

MR. ROGER WILLIAMS exhibited photographs of a boy showing this condition. The legs were so short that in the upright position the child's fingers touched the ground. No trace of femur or patella, or of their muscles, could be found on either side. Measurement from the right anterior superior spine to the internal malleolus, nine and a half inches; from the left anterior superior spine to inner malleolus, fourteen and a half inches.

Mr. JOHN WOOD mentioned the case of the "man-monkey" exhibited in London some years ago. He thought it showed how very useful limbs might be, even when one section was absent, and was an argument in favour of resection of joints.

Obstruction of Trachea by enlarged Glands.

Mr. G. H. MAKINS showed a specimen taken from the body of a boy, aged three, who had measles nine months previously, followed by abscess in the neck. Respiration difficult on exertion, slight stridor, expiration the most difficult, sinus at root of right neck. The dyspnœa increased, laryngoscopic examination difficult. Tracheotomy was performed, but the chest-walls still receded, with noisy, difficult expirations; a catheter was passed into left bronchus. Mother afterwards said the child had had difficulty in swallowing. The child lived two days. At the necropsy, just above the bifurcation was an ovoid mass of caseous bronchial glands softening. The diagnosis, after the operation, was assisted by the suppuration in the neck. Compression of the trachea was rare from this cause.

Dr. SEMON laid stress on the expiratory nature of the dyspnœa. He could not see how the enlarged glands could produce this. Gerhardt had shown that the larynx remained immovable when the disease was situated at the bifurcation of the trachea; when the larynx itself was affected, it moved up and down during respiration. He had supposed there might have been a pedunculated growth sucked in further to the trachea, and so cause the expiratory dyspnœa. At present this symptom was quite unexplained.

Mr. BLACK suggested that during expiration the capacity of the chest was diminished, and thus the glands would be pressed upon.

Dr. EWART thought that turgidity of veins might locally increase the pressure. Perforation of the trachea from the pressure of enlarged caseous glands was far from uncommon.

Dr. D. B. LEES asked whether there was any dulness in the chest in front or behind.

Mr. MAKINS thought that the tendency to collection of mucus would be below rather than above the tumour, and might have helped to cause the expiratory dyspnœa. There were no physical signs of the enlarged mediastinal glands.

A Natiform Skull.

Dr. NORMAN-MOORE showed this specimen, taken from a child twenty months old, who died under Dr. Church, at St. Bartholomew's Hospital. There were four large osteophytes around the anterior fontanelle, and several smaller ones on the supra-occipital region — when fresh, these were all bright red. There were no fissures about the mouth or anus, no beadings of the ribs, and no enlargement of the ends of the long bones. The spleen weighed six ounces; microscopically, the liver, spleen, and kidneys showed no increase of connective tissue. There was no amyloid disease. The child had never had snuffles or any rash. It had whooping-cough at the age of seven months, and had been losing flesh from that time. It only weighed ten pounds at death. There were no signs of specific disease in the mother—she had had no miscarriages. The child was one of six, three of whom were living—none were stillborn. It was certainly difficult in this case to be positive as to the influence which produced the osteophytes in the skull, the case suggesting that they might be due to malnutrition without any congenital taint.

Cerebral Tumour.

Dr. ILOTT said the specimen had been taken from a man, aged 25, a painter. He had been ill six weeks—anorexia, vertigo, vomiting; he was said to have fallen sometimes. His memory was impaired; there was tremor of facial muscles and arms; there was a blue line on the gums, and the abdomen was retracted. Two days later he had violent epileptiform convulsions, followed by coma and rigidity of right arm. After death, sinuses of dura mater full, excess of subarachnoid fluid, lateral ventricles dilated, ependyma roughened. There was a tumour of centrum ovale in right frontal lobe, bulging into the lateral ventricles; it was softening. It consisted of rounded nuclei: Dr. Goodhart called it a glioma. It was very vascular.

Dr. GOODHART mentioned as an interesting point that facial convulsions were the only symptoms. It probably involved the motor convolutions near the island of Reil, and was an instance of cerebral localisation.

Porencephalie.

Dr. B. G. MORRISON showed this specimen, taken from an infant healthy at birth; soon after he was attacked with convulsions; these recurred at intervals till death at age of eight months. At the necropsy there was much excess of fluid, the brain was much atrophied and compressed; there was also hydro-rachis. The right anterior and posterior lobes showed more wasting than elsewhere; the convolutions here were brownish yellow. On the left side, at the base, were three cysts—one at apex of temporo-sphenoidal lobe, two behind it, one also on right side. The vertex showed three in left frontal lobe; on right side was an elongated cyst in the middle of marginal convolution, also one in frontal lobe. Only two on the left side communicated with each other. There were no other visceral lesions. In the cord there was incipient sclerosis. The cystic walls also showed inflammatory changes. The cyst grew by spread of these inflammatory changes, followed by degenerations. There were two groups, according to Kundrat,

viz., congenital and extra-uterine cases. The changes followed the distribution of the middle cerebral artery.

Dr. Turner had examined this case for Dr. Morrison. He found apparently nothing but the cortical layer of the brain, as if the medullary part had been absorbed. At first, there were bundles running in from this cortical portion. The shrivelled-up part might be in that state from collapse of pre-existing cysts. The degeneration in the spinal cord was probably secondary to a previously occurring affection on the brain.

Dr. Hulk White doubted whether this was a case of porencephalie, because it was supposed usually that disease of the brain was the primary cause; whereas in this case there appeared to have been cysts in the ependyma probably at first.

Dr. Ewart had reported a case to this Society in 1879, in a man, aged 30. The cyst was in the frontal lobe on the right side, which sent out prolongations leading to ampulla-like dilatations packed with cyst membrane.

Dr. Money alluded to a case of atrophy of the right hemisphere with many cysts, and marked brownish yellow pigmentation which he attributed to a hæmorrhage. The case was in the last volume of the "Clinical Society Transactions."

Dr. O'Connor asked if there was any alteration in the shape of the skull.

Dr. Morrison did not think there was any communication between the cysts. He thought the case illustrated the extra-ventricular form of the disease. He did not think they could have resulted from hæmorrhages.

Tumour of the Thalamus.

Dr. Pye-Smith showed a specimen from the body of a boy, twelve years old. He had suffered from headache, vomiting, loss of sight. There was paresis of left arm, and ptosis of left eye. It had not been easy do more than make a diagnosis of cerebral tumour. After death a tubercular caseating tumour was found, also tubercular meningitis, and tuberculosis in the mediastinum. It occupied the right thalamus alone, not encroaching except into third ventricle, but had expanded more downwards, though not to any great extent. The paresis was only in the arm, there was no loss of sensation, no complaint of numbness. There were no convulsions. The ptosis had become more marked, but was not explained. The double optic neuritis could not be referred to the disease of the thalamus. It was to be desired that the word optic should be dropped, as it was really meaningless. The case bore out the view that the function of the thalamus was very limited.

Dr. Money thought that the existence of tubercular meningitis would interfere with the localising of this tumour.

Dr. Moore said that patients often had characteristic symptoms long before the tubercular meningitis could have commenced.

Dr. Beevor asked about the ptosis, and whether the internal capsule was at all interfered with.

Dr. Pye Smith said the tubercular meningitis was very slight, and quite recent; he thought not more than of two weeks' duration. He did not think the internal capsule was implicated, it certainly was not invaded or obviously pressed upon.

Cerebral Tumour.

Dr. Ormerod showed a specimen of tumour in the right cerebral hemisphere. It was rounded, the size of a large walnut, and projected a little. It involved the posterior part of the middle and lower temporo-sphenoidal convolutions, and the adjacent parts of the annectent gyri. The tumour was fairly well defined. It was a sarcoma with scanty stroma, and cells of two kinds; one set small and fusiform, the other much larger and multi-nucleated, like cells formed in ossifying bone. The latter varied in size and shape, many being rounded, others elongated. The patient was a man, aged 41, who had had fits for eighteen months, there was momentary loss of consciousness and general tremor. Latterly he had had one much more severe one. Something seemed to burst in his head, a hissing noise followed, he turned round several times to the right, fell unconscious, bit his tongue, and was convulsed on the left side. He was deaf from ear-disease, but his wife asserted that the deafness was worse since the severe fits. Optic neuritis subsequently appeared. Some physiologists placed the centre for hearing in the temporo-sphenoidal lobe. A tumour was not useful in localising functions, but still he laid some stress on the presence of the tumour in the temporo-sphenoidal lobe.

Dr. O'Connor asked if there had been headache or aphasia?

Dr. Ormerod replied there had been no aphasia.

Calcified Angioma of the Brain.

Dr. Goodhart showed this specimen from Mr. Bevan Lewis. A woman, aged 61, suffering from acute melancholia. There was a hard gritty mass in each hemisphere, about the size of a pigeon's egg, same colour as brain, not well defined. The calcareous spicules effervesced on addition of nitric acid. The tumour seemed to be composed almost entirely of calcified vessels.

Card Specimens.

Dr. Sharkey.—Primary carcinoma of kidney.

Dr. Frederick Taylor.—Sarcomatous tumour of the pituitary gland.

Mr. R. W. Parker.—Congenital absence of rectum. The child underwent colotomy on the eleventh day, and lived eight days.

Dr. F. C. Turner.—1. Ulceration of ileum and stomach, from a case of typhoid fever. 2. Cysts of the pia mater, with deformity of the brain.

Mr. H. H. Clutton.—Congenital papilloma occupying the line of the branchial fissure.

Mr. Morrant Baker.—Carcinoma of the tongue following gummatous ulceration.

HARVEIAN SOCIETY OF LONDON.

Thursday, March 6th, 1884.

Mr. George P. Field, President, in the Chair.

Some recent advances in Pelvic Surgery.

Mr. Lawson Tait, after a brief allusion to the history of abdominal section, said that during the last seven years great innovations had taken place, the most marked of all being the increased frequency of the operation, and its employment for purposes of diagnosis. In the author's series of operations, however, mere exploration did not exceed three per cent., exploration generally leading up to operation. The chief objection urged against such operations as removal of the appendages was to the effect that they sterilised and unsexed the patient. But matting together of the pelvic organs would produce sterility, and sexual intercourse could not be tolerated where abscess of the ovary existed. Passing to the subject of suppuration, the author dwelt upon the advantages of the treatment "from above" by free opening and drainage, in contrast with the method of aspiration per vaginam, which allowed matter to collect again and again. A consecutive series of 50 cases of abdominal sections, performed between March 30th, 1879, and June 13th, 1881, was submitted to the meeting. Three deaths had occurred in the series, one due to the infection of scarlet fever, the two others occasioned by severe hæmorrhage from myomata. The cases operated on were

grouped as follows: (1) Ovarian epilepsy, (2) pyo-salpinx, (3) hydro-salpinx, (4) menorrhagia, (5) myoma, (6) chronic adhesions, (7) pelvic abscesses. In hydro-salpinx somewhat troublesome adhesions had usually been encountered. In a case of intractable menorrhagia the ovary was studded with numerous small cysts. The author adverted to the occasional development of insanity after the removal of appendages. Relief from the pain and from the nervous symptoms in chronic ovarian affections had generally followed immediately after the operation, but in one case complete relief was not obtained until eight months had elapsed. Immediate stoppage of the menses was the usual result; this was not, however, invariably the case.

Dr. GODSON remarked that swellings previously diagnosed as inflamed ovaries, could no longer be accepted as such without hesitation; whilst, as regarded treatment, many such cases under the ordinary methods remained practically unrelieved. He entirely agreed with the author of the paper that it was impossible to define strictly the parametritis or perimetritis existing in a patient by examining her, both being frequently associated in the same case.

Mr. KNOWSLEY THORNTON expressed a general agreement with Mr. Tait as to the difficulty of diagnosis in these cases; also as to the sterility following the operations, but not as to the sexual condition remaining unaffected. He had been carefully enquiring into this subject, and found that the great majority were entirely unsexed, and, putting aside rare cases of third ovary, he believed that it was purely a question of complete or incomplete removal of ovarian tissue. He had also met with insanity after ovariotomy and kindred operations. On the question of exploration in abdominal and pelvic surgery, he expressed the opinion that the doctrine might be, and often was, carried too far. As an illustration of the freedom from any risks which might be supposed to arise from the use of strict Listerism in abdominal surgery, he might mention that he had just concluded two years' ovariotomy (73 cases) at the Samaritan Hospital without a single death.

Dr. BANTOCK acquiesced generally in the views expressed in the paper. He was glad to find that the author now agreed with him that the rupture of a hydro-salpinx should not be considered as a harmless accident. Even rupture of an ovarian cyst, though often disastrous, was sometimes unattended with any evil results.

Mr. BRYANT said that cases of insanity, temporary and permanent, had come under his observation after removal of the uterus and ovaries. He was strongly in favour of the diagnostic value of exploratory operations; he considered that in intestinal obstruction a similar rule should obtain to that which guided surgeons in dealing with external hernia.

In replying, Mr. LAWSON TAIT stated that acute melancholia was the type of insanity generally observed. He corroborated the statement as to the persistence of sexual feeling by citing an instance in which a uterine tumour and the appendages were completely removed in a woman who married, and was erotic. The continuance of menstruation in some cases where every portion of the ovary had been excised, entirely negatived the theory as to an interdependence between menstruation and ovulation. The author had found more risk to life from the employment of carbolic acid than from its abandonment.

AN ENORMOUS URINARY CALCULUS.—At a meeting of the Calcutta Medical Society, Dr. Cayley gave an account (*Indian Medical Gazette* for January) of a case of calculus occurring in a native, about 50 years of age, who had for some three years suffered from symptoms of stone, which of late had become very urgent. Lateral lithotomy was attempted, but could not be executed on account of the great depth of the perinæum, and the large size of the calculus. Even after the suprapubic operation had been undertaken, its extraction was found very difficult, as it nearly filled the bladder. When removed, it weighed 25½ ounces. The patient died two days after the operation, and no autopsy was permitted.

GENERAL CORRESPONDENCE.

THE PROPOSED CONVALESCENT HOSPITAL OF THE METROPOLITAN ASYLUMS BOARD.

[To the Editor of the Medical Times.]

SIR,—In your leader of 23rd February, upon the above subject, you remark: "We think that, as the site concerned comprises more than 36 acres, the Southgate Local Board need not have opposed the erection of the hospital, even had it been intended for the use of small-pox convalescents, as well as for convalescents from fever." Your opinion, thus expressed, incidentally but entirely corroborates views which I vainly endeavoured to impress upon the managers, when the purchase of the Winchmore Hill site was brought before the Metropolitan Asylums Board, on the 5th and 19th of January last. I must premise that for many months previously the Board had been in possession of 134 acres at their Gore Farm estate, near Darenth, and that it had been practically determined to set apart 24 acres thereof for the erection thereon of a hospital or tents for about 1,000 small-pox convalescent patients. Whilst fully recognising the importance of a convalescent hospital in the after-treatment of fever-patients, my contention, however, was: (1) that until Parliament had constituted the Asylums Board the sole authority for the care of all the infectious diseases of the metropolis, one such hospital was all-sufficient for pauper requirements; and (2) that it was unadvisable and unnecessary to spend 15,000*l.* in the purchase of land at Winchmore Hill, whilst the Board had already in their possession at least 100 spare acres on their estate at Gore Farm.

In your pages I need only refer to the medical objection started against my proposition. I pointed out that, considering during the last ten years the Board had been conjointly treating cases of *acute* small-pox and of *acute* fever with comparative respective immunity on less than ten acres of ground, it was surely reasonable to suppose that *convalescent* fever and *convalescent* small-pox patients could, with perfect immunity, be conjointly treated on 134 acres of ground. Otherwise the Board were in this dilemma:—either the managers had, with the concurrence of the Local Government Board, purchased at least 100 acres too much at Gore Farm, or the 36 acres at Winchmore Hill, surrounded by more houses than the former, were manifestly too few on which to erect a Convalescent Fever Hospital. Any one conversant with the subject would admit that, with the further precautions of placing a broad belt of trees, and of erecting a high wall (to prevent intercommunication) between the two hospitals, whilst the airing grounds of each were on the distal aspects of the respective buildings, at least 1,000 of the convalescents from each of the two diseases, and their administrative staff, might with safety be located on 134 acres of land on the northern heights of Kent.

Even with a knowledge that the sewage of this number would have had to be utilised on the ground, it cannot, in the face of experience, be said that the number would have been excessive. The Beddington Sewage Farm, near Croydon, has an area of about 540 acres, of which 450 acres are regularly sewaged. The farm purifies the sewage of about 63,000 persons.[1] Moreover, in a printed letter now before me, addressed on November 29th, 1883, by Dr. Alfred Carpenter "to the Mayor and Corporation of Croydon," we are told, that, provided such plants are grown which will effect the purification of the sewage most expeditiously, one acre, if worked efficiently, should thus dispose of the sewage of 300 persons. "There is no doubt but that rye-grass is the staple which is alone fitted to bring about this object." Therefore ten acres of rye-grass always in constant growth, would have enabled the managers of the Metropolitan Asylums Board to have accommodated

1 "Inspection of Beddington Sewage Farm by Members of International Medical Congress, 1881," Dr. Alfred Carpenter.

3,000 persons on their Gore Farm estate. Furthermore, we learn that "in the years 1875–6 the excreta of at least 1,000 cases of enteric fever were utilised on the (Beddington Sewage) farm. In the majority of the cases the excreta were certainly not disinfected, and that had they been capable of setting up the disease, some of the 65 persons at that time in the employ of the Local Board must have suffered from the infection . . . . and I could not hear of any person suffering from the disease, whose avocation brought him on to the fields, and this included some 60 to 70 other persons. . . . The neighbourhood is not subject to outbreaks more than any other district. . . . ."[2]

I am, Sir, Yours, &c.,

ROBERT FOWLER, M.D.

12, *Old Burlington Street, W.*
March 8th, 1884.

EVERY MAN HIS OWN MEDICINE CHEST.

[To the Editor of the Medical Times.]

SIR,—Every reader will thank you for your notice of the discussion by the New Military Medical Society of Woolwich, as to how antiseptic surgery may be carried out on the field of battle and in war; and all will join you in the hope that some practical outcome will be the result of this discussion. But, surely, the suggestion made by Dr. Lesser in the *Centralblatt für Chirurgie*. ought to be at once "declined with thanks." He would give every soldier one cartridge-case out of every twenty, filled with antiseptic powder, and provide him in addition with a bandage soaked in spermaceti, a little absorbent wool, and a three-cornered handkerchief. He asserts that "in this way the cartridge which carries death for the enemy, carries for us the means of healing wounds antiseptically, and so saves the lives and health of our wounded soldiers." *There can be no good reason for allowing the soldier to carry medical appliances about his person if the Army Medical Department be properly organised.* The transport which can carry a sufficient field-hospital equipment, may also be calculated to bear the extra weight of antiseptic dressings, spermaceti bandages, and three-cornered handkerchiefs by the thousand. It is not well that a soldier should go into action encumbered with articles calculated only to save his own precious life. The less he thinks of his own possible wounds the happier he will feel, and he had better concentrate his thoughts on the injuries he means to inflict upon his foes. Of course the time may come when the Medical Department may be deprived entirely of all transport. In the evidence given before Lord Morley's committee, we see that Medical Transport is considered by military men quite a secondary matter, and it might easily happen that there would be none available. Lord Wolseley is entirely opposed to having "a staff of transport" attached to the Medical Department, and probably there are many combatants who would prefer to see the doctors carrying all their burdens on their own backs, and in that case the private soldiers might carry some extra weight to oblige the medical officer. But, then, one need not stop at antiseptic dressings. Why should not Tommy Atkins carry a set of splints, a pulley or two, a neat saw, and a sharp amputating knife? He might be instructed not to use the knife to cut his tobacco, nor the saw to shape a tent-peg. It is possible that he might even learn not to jamb his rifle with an antiseptic cartridge. At present Dr. Lesser's views are not suitable for an English army. We have still an Army Medical Department. It is different in Germany, perhaps, for, as Captain Baron Hoiningen Huene told the War Office Committee, "the combatant or military officers in the German army are taught the principles of sanitary science." They are instructed in *dressing the wounded* and the treatment of sunstroke, and also in the treatment of drowned men. O happy Germany which can afford to get rid of a Medical Department, and enable every combatant to be his own medicine-chest, field companion, and medical attendant! In England we must wait.

I am, Sir, Yours, &c.,

SENEX.

SHIP SURGEONS.

[To the Editor of the Medical Times.]

SIR,—I have to thank you for drawing my attention in a leader in your edition of January 5th, 1884, to Dr. Domett Stone's letter to the *Times*; I think Dr. Stone misstates the case when he says that the superintendents of mercantile marine do not require a ship's surgeon to produce evidence of possessing legal qualifications. For my personal experience is opposed to this, in London at least, where a surgeon, if his name is not on the medical register—a copy of which lies upon the table of the shipping office—has to produce his certificate of registration for the year in which his name could not appear in the current register. Regulations may be more laxly carried out in Dundee, but I believe the case there to be as follows:—There are always a number of "chronics" at every medical school, and some of these failing to pass the "half," or any examination, often repair to the ports whence whalers sail, and enter into an agreement with the captain of one of these vessels, to give their medical services, such as they are, in return for a voyage and modicum of pay or share in the proceeds of the fishing. As no one can go to sea, not being a passenger, without appearing on the ship's articles, and as no one can ship as surgeon under the Merchant Shipping Act, without legal qualifications, the would-be dresser is shipped under the title of steward or something of that kind; and, whalers not being required to carry surgeons, no one suffers hereby unless it be, perhaps, the unfortunate patients whose case, however, must be better, take it as you will, than if only the captain or mate administered to their bodily ailments, since a number of the "chronics" are really *practical* men. I know a case in point where the pseudo-surgeon, in virtue of his experience gained in whalers, has sailed on a yachting cruise with some notabilities who chose to trust their valuable persons to the care of an unqualified person, rather than pay for the services of a registered practitioner. The skipper who takes a dresser, then, may be considered a philanthropist, for he does more than he is required to do by the law. Some smart youths, also, who have passed through the curriculum for a degree, but are prevented from taking it through being too young (as is the case with some examining bodies) now and then take trips in whalers under these conditions, or go as assistants to general practitioners. Between these two modes of employing spare time, I fail to see any difference; if allowable in the one instance, why not in the other? But there is no doubt that a mercantile marine service, as suggested by Dr. Stone, is most desirable, and it would be a most admirable check upon the ship owners, who at present can impose any conditions they please upon the unfortunate men who from choice or necessity, and that, sometimes the direst, have to seek service at their hands. Every surgeon engaged should be so through the medium of this projected association, and a few weeks of steady refusal to supply surgeons unless under improved conditions would very speedily solve the question. No large passenger vessel or mail steamer can leave a port without her surgeon, and if the companies were placed in a condition similar to that of the Army Medical Department some few years ago, it would mean immediate ruin, yet they ignore this unpleasant truth, and can actually force men to sign agreements whereby they will lose 25 per cent. of their miserable pittance when serving on a foreign station, and have to insure their lives for one or two hundred pounds at a colossal premium, which I will not here mention for reasons of my own. I predict that immediate improvement would take place were this association once started, and I shall be most happy to give it my staunch support. I can also promise that of numbers of my colleagues now abroad, and I hope, on arriving in London, to be able to confer with any gentlemen disposed to organise the service, which might well start under the

auspices of your influential medical journal. At present there are a great number of younger professional brethren who, scarcely fledged, take wing for a seaport and ship under any conditions, through ignorance and, perhaps, from the necessity of gaining a livlihood at all hazards. It would be the duty of the association to see that the conditions under which these young surgeons were shipped were of a nature best calculated to raise the status of the profession, and it would be necessary to have branches at all the ports to watch over its interests, and prevent the ignorant from being imposed upon. By means of these young surgeons, the shipowners can always grind down those who have elected to practise in ships, and the demand for willing hands to take the place of the refractory, or, as I have been myself once called, "objectionable" characters is always responded to by hundreds of applicants. The terms *refractory* and *objectionable* are applied, as I had better explain, when a surgeon does not wish to proceed to sea within eight days of his landing after a long voyage, or refuses to take charge of a ship which he knows is not so well suited to his requirements as the one he has charge of at the moment, and so on. The only difficulties in the way of forming the association are to be found in the appointment of a standing committee and officers, for the members would necessarily be always on the move; but this could be obviated easily if some of our brethren, who do *not* go down to the sea in ships, would lend their valuable assistance, in doing which they would be performing as truly benevolent an action as any of those which their modesty never permits the outer world to view, and which they yet perform almost daily. Legislation would be perfectly superfluous in the face of such an organisation for mutual protection, as all that we ask for is fair play, and if that is not served out, our services can be given to those employers whose good sense has come to their rescue in time. Hoping to hear more of the project when I arrive in London,

I am, Sir,
Yours, &c.,
A SHIP'S SURGEON.

Port Said, February 12th, 1884.

[Such an organisation as is sketched by our correspondent would have our cordial support.

ED. *Medical Times.*]

MEDICAL NEWS.

MEDICAL ACT AMENDMENT BILL.

This Bill passed through Committee in the House of Lords on Thursday afternoon. ON the motion to go into Committee, LORD BALFOUR said his objections to the Bill were fully discussed last Session, and he had not placed on the paper the same amendments as last year, but he wished to advise the House, that the objections of the Scotch Universities to the Bill were not lessened. This Bill, if passed in its present form, would tend to lower the standard of medical examination in Scotland. The DUKE OF RICHMOND was justified in saying that there was dissatisfaction in Scotland with the Bill. He trusted, however, that the Government would press this Bill to a division, and they would do so if they had a proper regard for the medical profession and were in earnest. LORD CARLINGFORD replied that it was very difficult to navigate a Bill of this kind through Parliament, as the Government had to steer through a shoal of quicksands; and the difficulties were now increased by the jealousy of the University of Edinburgh and those in the provinces. The House then went into Committee, and the Bill as amended passed through Committee.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 13, 1884:—

Charlesworth, Geo. Henry, Tonsley Hill, S.W.
Clark, Simon Prince, Cumberland Street, Glasgow.
Dodd, Walter Harry, Petherton Road, Canonbury, N.
Gould, Ernest Edward, Clifton Hill, Exeter.
Hugill, Geo. Fredk., Rosedale, Chislehurst.
Jenkins, John, Royal Infirmary, Bristol.
Menzies, Herbert Jas., Gurndur Road, W.
Robbs, Chas. Edwd., Powis Square, W.

UNIVERSITY OF CAMBRIDGE.—In May next a Professor of Pathology will be elected, with a stipend of 800*l.* a year. Soon afterwards four Medical and Surgical Lecturers will be appointed, with stipends of 50*l.*; one of them to take the subject of Midwifery. The electors to the Professorship are—The Vice-Chancellor, Sir James Paget, Dr. J. F. Payne, Dr. Burdon Sanderson, Dr. Paget, Dr. Humphry, Dr. Latham, Dr. Gaskell, and Dr. M. Foster.

THE MOSCOW UNIVERSITY IN 1883.—In this University there were altogether 2,799 students, 1,316 of these being medical. The number of professors amounted to 81, 32 of them belonging to the medical faculty. There were also eight *privat docenten* almost all of whom belonged to the medical faculty.—*St. Petersburger Medicinische Wochenschrift*, March 1st.

EDINBURGH UNIVERSITY TERCENTENERY.—The following are the names of some of the delegates who have intimated their intention of being present (asterisks indicate those who are to receive honorary degrees):—Prof. Ask, University of Lund, Sweden; Dr. Atherton, University of New Brunswick; Dr. G. W. Balfour, President of the Royal College of Physicians, Edinburgh; Prof. Ball, School of Medicine, Paris; Sir Risdon Bennett, Royal College of Physicians, London; Dr. J. S. Bristowe, St. Thomas's Hospital, London; Dr. W. B. Carpenter, C.B., University of London; Dr. D. Doijer, Prof. of Ophthalmology, University of Leyden; Mr. J. E. Erichsen, University College, London; Dr. Andrew Fergus, Faculty of Physicians and Surgeons, Glasgow; * Rev. Samuel Haughton, M.D., F.R.S., Trinity College, Dublin; * Mr. John Marshall, Royal College of Surgeons, London; M. Louis Pasteur, Académie des Sciences; Dr. E. H. Sieveking, Edinburgh University Club of London; Dr. John Smith, Royal College of Surgeons, Edinburgh; Dr. John Thorburn, M.D., Edinburgh University Club of Manchester; Prof. Rudolf Virchow, M.D., Royal Academy of Science, Berlin. The following are amongst those who receive the honorary degree of LL.D.:—Dr. Fordyce Barker, New York; Sir William Bowman, Bart.; Professor Chauveau, Lyons; Sir Andrew Clark, Bart.; Professor Donders, Utrecht, Holland; Professor Erichsen; Dr. D. Rutherford Haldane; Rev. Samuel Haughton, M.D., Dublin; Professor Hermite, Académie des Sciences, Paris; Professor H. von Helmholtz, Berlin; Sir Wm. Jenner, Bart.; Dr. Thomas Keith; Professor von Kolliker, Würzburg; Mr. John Marshall; Dr. H. Maudsley; Sir James Paget, Bart.; Professor B. J. Stokvis, Amsterdam; Professor Virchow, Berlin; and Dr. Patrick Heron Watson, M.D.

THE HOSPITALS' ASSOCIATION.—It is now arranged that the evening meetings of the Association shall be held at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square. The first will take place on Wednesday next, when Mr. William J. Nixon, House Governor of the London Hospital, will read a paper, "On Difficulties associated with the Administration of the Out-Patient Department, and how best to deal with them." Sir Andrew Clark, Bart., will preside. Papers on the following subjects will be contributed during the present session:—April 23rd, "How far our Hospitals should be Training Schools for Nurses." May 21st, "How the Hospital Sunday and Saturday Funds can be made more Useful to the Hospitals." June 18, "Is it desirable that Hospitals should be made Self-supporting; and, if so, to what extent?" Applications for membership should be addressed to the Secretary, Mr. J. L. Clifford Smith, at the office, 1, Adam-street, Adelphi, W.C.

Gonville and Caius College.—The Thruston Prize will be awarded at the end of the present academical year. The prize, about 54*l.* (as money, or in any other form that may be thought best) is given triennially "to that member of the College who has published, in the course of the preceding three years, the best original investigation in Physiology (including Physiological Chemistry), Pathology, or Practical Medicine." Publications or notice of publications may be sent to the Master.

Glasgow Ophthalmic Institution. — The Annual Meeting of the Glasgow Ophthalmic Institution was held on the 10th instant. The medical and financial reports of the institution are highly satisfactory. There were treated during the year 3,012 cases, of which number 385 were indoor patients, and 2,627 dispensary patients. Of the 3,012 cases treated during the year, 2,076 were cured, 84 relieved, and 52 dismissed as incurable. Many of the latter were of such a nature as to be beyond surgical skill, before applying to the institution for aid. There were 612 operations during the year. The number of patients treated since the opening of the institution in 1870, was 43,730, and of these 42,189 had been cured or relieved. The income during the year was 1,346*l.* 19*s.* 8*d.*, and after the annual outlay, a balance of 128*l.* 5*s.* 5*d.* was at the credit of the institution. Sir James Watson who moved the adoption of the report, spoke in high terms of the efficiency of the institution and of the appreciation in which it is held by the community, and especially by the working classes who are benefited by its operations; this they have shown by their contributions to its funds Indeed, during the past year, 254 workshops contributed towards its support, from which source two-thirds of the income is derived. Sir James Watson and Dr. Wolfe referred in very feeling terms to the great loss the institution had sustained in the death of Mr. James White, of Overtown, who had been the chairman of the institution since its commencement. He was a princely giver, and the head of all philanthropic movements in Glasgow and the West of Scotland.

The Odonto-Chirurgical Society of Scotland.—At the annual meeting, held on the 13th, in Edinburgh, Mr. Bowman Macleod read a paper on "Chloroform and other Anæsthetics: their relative value in dental Operations." He said he had for the longer operations taken recourse to chloroform in the interests of his patients; and, notwithstanding the percentage of recorded accidents, it was, when carefully used, the best and the most reliable abrogator of pain which we had as yet at our disposal. There was a lurking danger ever present in its use, which they must be prepared to meet, and against the approach of which they had carefully to guard; but with chloroform he had fewer cases which had caused him anxiety than with any of the other anæsthetics. In the course of the discussion, Dr. Smith related various cases in which death had occurred in operations in which neither chloroform nor any anæsthetic had been used, and said that had chloroform been used in those cases, death would have occurred all the same, and chloroform would have got the blame. He did not say that deaths had not occurred from the use of chloroform, because he believed that they would never be able to use anæsthetics—they would never be able to put man, or any other animal, into such an unnatural position as not to feel the extreme pain of taking out a tooth—without entailing a certain amount of danger.

Charitable Bequests.—Mr. James White, of Overtown, a prominent merchant in Glasgow, who died recently, has bequeathed 5,000*l.* to the Glasgow Royal Infirmary, and 5,000*l.* to the Glasgow Western Infirmary.

A "Lucid" Judgment.—The French Court of Cassation has quashed a judgment obtained some time ago by the proprietress of an hotel near the Sorbonne, awarding damages for disturbance to her trade caused by the howlings of dogs undergoing vivisection at that institution. The Court holds that the physiological experiments in question constitute a branch of instruction given by the State, and that M. Paul Bert, against whom the judgment was obtained, and other professors of every rank accomplish by such experiments a public service.

The Paris Registration Returns for 1883.—In Dr. Bertillon's report it is stated that 57,024 deaths took place during the year (9,630 of the number were under the first year), while in 1882 they numbered 58,702. This difference of 1,678 deaths in favour of 1883 was entirely due to the amelioration of the state of the public health during the second half of 1883. The births which in 1882 numbered 62,518, increased in 1883 to 64,190, being a difference of 1,609 in favour of 1883. Of these 64,190 births, 32,565 are male, and 31,625 female. They do not comprise children born dead, or who die before they are registered (*i.e.*, within 24 hours). These amount to 4,994, viz., 2,783 males, and 2,210 female children. Of the 69,184 children born living or dead, 50,567 (73·09 per cent.) were legitimate, and 18,617 (26·91 per cent.) illegitimate. The number of marriages in 1883 was 21,168.

Diphtheria at Odessa.—A general meeting of the city authorities was held on February 23rd, for the adoption of special measures in order to arrest or minimise the alarming mortality from diphtheria in Odessa and its environs. The disease has been, in a greater or less degree, epidemic in the city for the last twelve years. There are at present special hospital barracks set apart for the reception of patients, and attended by trained nurses and sisters of charity, but to these establishments the better class and wealthy citizens will not send their children. If one of a family of children catch the disease, the other members are for a time removed to the residence of friends, the patient succumbs, and the other children are brought back, and, sooner or later, further victims fall. A sum of money has now been voted, and subscriptions invited, in order to establish diphtheria hospitals, on the system of sanitary hotels, where a relative of the patient will be accommodated at a moderate charge, and a thorough system of medical inspection, removal of patients, and disinfection of the poorer and crowded domiciles will be carried out.

Health of British Army in India.—From the annual report of the Sanitary Commissioner with the Government of India, we gather that the health of the European Army was unusually good during the year 1882. As regards the Bengal Army, the results are described as favourable, whilst in the Madras Army and the Bombay Army they are said to have been very favourable. Taking the three Presidencies Bengal, Madras, Bombay, in that order, we find that the death-ratio per thousand from the chief diseases was as follows:—enteric fever 2·9, 2·09, 1·9; hepatitis 1·48, 1·72, ·81; cholera 1·28, ·82, ·63; dysentery ·77, ·36, ·18. The year was singularly healthy as regards cholera, there having been only 98 cases throughout the whole army in India, of which 61 died; not a single case of cholera occurred amongst the troops in the Punjâb, in the Hill stations, or in the convalescent depôts. Small-pox was more prevalent than in 1881, and there was a marked rise in the total number of cases of enteric fever, especially in the Bengal Presidency.

Suicides in New York.—The number of suicides during last year was 161; of these, 78 were married, 43 single, and 24 widowed or divorced. The list includes 134 males and 27 females. Nine of them were less than 20 years of age, 30 between 20 and 30, 44 between 40 and 50, 29 between 50 and 60, 7 between 60 and 70, while 8 suicides became tired of life in the eighth decade. Among the nationalities, Germans came first with 70 suicides. Shooting was the favourite method of killing, since it was resorted to in 56 instances. There were 19 hangings, 15 stabbings and cuttings, 12 drownings, and 11 falls from high places. Paris-green was in high demand among poisons, 18 suicides choosing it, while 7 took opium.—*New York Medical Record*, January 5th.

National Health Society.—The first meeting of the special committee of the National Health Society to establish a conference on "School Hygiene," during the International Health Exhibition, took place at the Society's Offices, 44, Berners-street, on the 12th instant. It was arranged that papers on various topics relating to school life and training should be read, and discussions invited. All those interested in the subject are requested to communicate with the Secretary.

GRESHAM LECTURES.—Dr. Symes Thompson will lecture on the 25th instant, and the three following days, at 6 o'clock in the International Health Exhibition.

SMALL-POX IN MADRAS.—A severe epidemic of small-pox is raging in Madras, the death-rate in the city being higher than has ever been reached since the famine.

APPOINTMENTS.

BARR, THOMAS, M.D., F.F.P.S.—Aural Surgeon, and Lecturer on Aural Surgery, to the Glasgow Hospital and Dispensary for the Diseases of the Ear, *vice* Dr. J. Patterson Cassells.

EDWARDS, JOSHUA P., L.F.P. and S. Glas., L.S.A. Lond.—Medical Officer to the Tunstall District, Wolstanton and Burslem Union.

ERSKINE, JAMES, M.A., M.B., C.M.—Assistant Aural Surgeon to the Glasgow Hospital and Dispensary for the Diseases of the Ear.

GIBB, WILLIAM, L.R.C.P., L.R.C.S.—Extra Medical Assistant to the Dundee Royal Infirmary.

GOSTLING, THOMAS PRESTON, late House-Surgeon to University College Hospital, Obstetric Assistant to the same Institution.

HYRONS, E. A., M.R.C.S.—Junior House Surgeon to the Borough Hospital, Birkenhead, *vice* Richardson, promoted.

MAYO, FRANK H., M.R.C.S., L.R.C.P. — House Surgeon to the General Infirmary, Leeds.

MEARS, W. P., M.D.—Examiner in Anatomy to the University of Durham.

NANCE, H. CHESTER, M.R.C.S., F.R.C.P., L.S.A.—Senior Resident Medical Officer to the Hospital for Sick Children, Pendlebury, Manchester.

RITCHIE, Dr.—Medical Officer to the Parish of Cathcart, near Glasgow.

SPROULLE, THOS. W., L.R.C.S. Ire., L.K. and Q.C.P. Ire.—Medical Officer to the Mirfield District, Dewsbury Union.

STEWART, C. W., M.D.—Physician on the Staff of Anderson's College Dispensary, Glasgow.

WHYTE, JOHN MACKIE, M.A., M.B., M.R.C.S., Medical Assistant to the Dundee Royal Infirmary, *vice* Duncan J. Reid, M.B., appointed Dispensary Surgeon.

WYER, OTHO F., M.D.—Honorary Physician to the Warneford, Leamington, and South Warwickshire Hopital, Leamington, *vice* Thomas A. Carter, M.D., F.R.C.P., resigned.

VACANCIES.

BRIGHTON AND HOVE LYING-IN INSTITUTION.—House Surgeon. Salary, £120 per annum, with furnished apartments, coals, gas, and attendance. Candidates must be members of one of the Royal Colleges of Surgeons of Great Britain and Ireland, and Licentiates of the Royal College of Physicians of London, or of the Apothecaries' Company in London, duly registered under the Medical Act, unmarried, and under 30 years of age. Diplomas, testimonials, and copy of registration to be forwarded to the Secretary, before April 4th. The election will take place on Friday, May 2nd.

EDMONTON UNION.—Medical Officer to the South Hornsey District, in succession to Mr. John Deane, resigned. Salary, £36 5*s.* per annum.

FLINTSHIRE DISPENSARY.—House Surgeon. Salary, £100 per annum, with furnished house, &c. Candidates' names must appear on the Medical Register, as being possessed of Medical and Surgical qualifications, and they must produce evidence of good moral character. Private practice prohibited. Candidates conversant with the Welsh language preferred. Applications, with testimonials, to be sent to the Secretary, on or before April 15th. The election will take place on April 30th.

MORPETH DISPENSARY.—Resident Medical Officer. Salary, £100 per annum, with furnished apartments, coals, and gas. Candidates must be duly qualified, and unmarried. Applications and testimonials to be sent to Mr. D. W. Greenwood, Morpeth, on or before April 5th.

REDRUTH UNION.—Medical Officer to the Guinear District, in succession to Mr. S. Farmer, resigned. Area, 10,003 acres. Population, 6,424. Salary, £32 per annum.

STRATFORD-ON-AVON UNION.—Medical Officer to the Alveston and Welford Districts, and the Workhouse, in succession to Mr. John Gairdner, resigned. Alveston District: Area, 11,798 acres. Population, 2,405. Salary, £55 per annum. Welford District: Area, 11,569 acres. Population, 2,012. Salary, £55 per annum. Salary for Workhouse, £66 per annum.

WEST LONDON HOSPITAL, HAMMERSMITH.—Surgeon. Candidates must be Fellows of one of the Royal Colleges of Surgeons of London, Edinburgh, or Dublin, and not practising Midwifery or Pharmacy. They must attend, if practicable, at the meeting of the Medical Council, on Tuesday, 1st April, at 3·30 o'clock p.m. Applications and testimonials, to be sent to the Secretary, on or before March 31st. Applications are also invited, in the event of an Assistant Surgeon being elected, for an Assistant Surgeon.

WOLVERHAMPTON UNION.—Medical Officer to the Fifth District, in succession to Mr. William M. Hancox, resigned. Area, 848 acres. Population, 11,360. Salary, £73 per annum.

DEATHS.

ARCHER, CHARLES, M.D., Surgeon-General, late of the Bengal Medical Department, on March 17, aged 66.

AYERST, JAMES SMITH, M.D., at Stanbury, Torquay, on March 15, aged 59.

BALDING, MARGARET, eldest surviving daughter of the late James Balding, M.R.C.S., L.S.A., at Barkway, Herts, on March 13.

CORBOULD, FRANCIS JOHN, M.D., at Somers-road, Reigate, on March 12, aged 65.

FURLONG, SURGEON-GENERAL, retired, at Dolhaidd, Carmarthenshire, on March 16, aged 61.

HOGG, HENRY LEE, M.R.C.S., L.S.A., at Cleobury Mortimer, Salop, on March 3, aged 70.

HOOD, THOMAS, M.R.C.S., L.R.C.P., L.S.A., at the Château de l'Espagnerie, Wimille, Pas-de-Calais, France, on March 10.

LEREW, WILLIAM KIRBY, M.R.C.S., L.S.A., at 4, Clifton-terrace, Maida-vale, W., on March 16, aged 69.

REYNOLDS, SAMUEL, F.R.C.S., at Beckenham, on March 15, in his 88th year.

ROBINSON, JOHN, M.R.C.S., at 32, Devonshire-street, Portland-place, W., on March 16, aged 72.

TOULMIN, FRANCIS, F.R.C.S., at Upper Clapton, on March 13, in his 82nd year.

NOTES, QUERIES, AND REPLIES.

Immigration into France.—Of the 37,672,048 inhabitants of France, 1,101,090 are foreigners, of whom 432,265 are from Belgium, 240,733 from Italy, 81,986 from Germany, 73,781 from Spain, 66,281 from Switzerland, and only 37,006 from the British Isles. The number of naturalised foreigners is only 77,046.

Prof. Gross's "Hair-Tonic." — ℞ Tinct. Cantharid. ℥jss; Tinct. Capsici ℿlxx; Glycerini ℥ss; Aquæ Coloniensis ad ℥vi.—*Philadelphia Medical Reporter*, March 1.

Municipal Liberality.—At a meeting of the Court of Common Council, held in the Guildhall, the Lord Mayor presiding, the Court made, amongst other liberal grants to charitable institutions, one of £315 to the London Hospital, Whitechapel Road.

British Home for Incurables.—At the festival dinner of this excellent Institution, on Tuesday, the subscriptions in aid of the funds were announced as amounting to the large sum of £3,100.

Mr. F. S. Eve, F.R.C.S., will give his last Demonstration at the College of Surgeons, "On Some Important Points in Connexion with the Surgery of the Urinary Organs," this day (Friday) at 4 o'clock.

Dental Examinations.—The following were the questions submitted to the Candidates at the last examination for the Licence in Dental Surgery of the Royal College of Surgeons, viz.:—

DENTAL ANATOMY AND PHYSIOLOGY.—1. Give the general Dental Formula of Marsupialia. Point out the leading resemblances and differences between their teeth and those of Placental Mammals, illustrating your answer by reference to an animal belonging to each class. 2. Describe the structure and development of Cementum, comparing it with Bone. What is its general distribution upon the teeth of Mammalia? 3. Name the periods of (i.) commencement of Calcification of the several Permanent Teeth, (ii.) of Eruption of the same, (iii.) (approximately) of completion of their Roots.

DENTAL SURGERY AND PATHOLOGY.—1. If during extraction a Tooth slip into the Throat, what complications may arise? what symptoms will denote its position? and what will be the appropriate treatment? 2. Mention the symptoms on which you would rely, and the tests you would employ, in diagnosing Odontalgia from Neuralgia. 3. Describe the "transparent zone" of Dental Caries. What evidence exists as to its nature?

ANATOMY AND PHYSIOLOGY.—1. Give the precise attachments of all the Muscles connected with the Lower Jaw, exclusive of those of expression. 2. Mention the Nerves distributed to the Mouth, and state what you know respecting the functions attributed to each.

SURGERY AND PATHOLOGY.—1. Enumerate the several causes which prevent or hinder Movement of the Lower Jaw, and indicate the treatment you consider appropriate to each case. 2. Describe the Pathological and Clinical differences between an Epithelioma and an Epulis.

Dr. R. H. Gale, Anchorage, Kentucky, U.S.A.—We cannot comply with your request, and it will, perhaps, be more to the purpose to refer you to the *American Psychological Journal* for October 1883. We trust you will be able to tell us (and that we in turn shall be able to tell our readers) that the whole thing is a clever hoax, and that we, as well as other people, have been taken in by it.

COMMUNICATIONS RECEIVED—

Prof. Paget, F.R.S., Cambridge; Miss Lankester, London; Dr. Mercier, Dartford; Mr. Henry C. Burdett, London; The Clerk to the Urban Sanitary Authority, Hastings; The Secretary, Apothecaries' Society, London; Dr. Clifford Allbutt, Leeds; The Secretary, International Health Exhibition, London; Mr. I. B. Seely, London; Dr. Octavius Sturges, London; Dr. G. Coates, London; Mr. W. J. Spence, Bradford; Mr. W. J. Milles, London; Mr. J. Roche, Kingstown; Mr. Wynter Blyth, London; Dr. Shelly, Hertford; Dr. Wolfe, Glasgow; Mr. J. L. Foulds, Glasgow; Dr. Wilks, London; The Secretary, Medical Life Assurance Society, London; Dr. Veale, London; Mr. Becher, London; Mr. J. G. Thrupp, London; Mr. Chatto, London; Dr. E. Symes Thompson, London; Dr. D. Sime, London; Dr. G. B. Longstaff, London; The Hon. Secretary, Medical Society of London; The Secretary, Royal Institution of London; The Director, Anthropological Institute of Great Britain and Ireland, London; The Registrar-General, Edinburgh; The Secretary, The Parkes Museum, London; The Hon. Secretary, Clinical Society of London; Mr. Edmund Owen, London; Dr. Collier, London; Dr. Willoughby, London; Dr. Tirard, London; The Hon. Secretary, Hunterian Society, London; Messrs. F. W. Reynolds & Co., London; Dr. Burney Yeo, London; The Secretary, Statistical Society, London; The Secretary, Royal Medical and Chirurgical Society, London; Mr. H. R. O. Cross, London; The Secretary, The Hospitals Association, London; Mr. J. F. W. Bacot, Seaton, Devon.

BOOKS RECEIVED—

Annual Report of the Cumberland and Westmoreland Lunatic Asylum for 1883—Injuries and Diseases of the Jaws, by Christopher Heath, F.R.C.S.—Clinical Lectures on Important Symptoms, by Thomas Grainger Stewart, M.D.—Principes de Thérapeutique Générale, par J. B. Fonssagrives—Annual Report of the Sanitary Condition of the Township of Stretford for 1883.—The Gold-headed Cane, by W. Munk, M.D., F.S.A.—Atlas of Female Pelvic Anatomy, by Dr. Berry Hart, M.D., F.R.C.P.—Transactions of the American Ophthalmological Society—A Handy-Book on Window Gardening, by H. C. APPOINTMENTS FOR THE WEEK.

March 22. *Saturday* (*this day*).

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Royal Institution, 3 p.m.—Capt. Abney, "Photographic Action."

24. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Medical Society of London, 8 p.m.—Dr. Cavafy, "On Erysipelas with Low Temperature;" Dr. D. W. Finlay, "On a Case of Opium-Poisoning;" Dr. A. W. Walters, "Meteorological Observations at Davos;" Dr. D. W. Cullimore will show "A Case of Post-Diphtheritic Paralysis."

25. *Tuesday*.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Anthropological Institute of Great Britain and Ireland, 8 p.m.—The Institute will meet at 4, St. Martin's Place, W.C., when the following Papers will be read:—(1) The Right Hon. the Earl of Wharncliffe, "Exhibition of a Flint Implement from the North Riding of Yorkshire;" (2) F. G. Hilton Price, Esq., F.S.A., "Note on some Ancient Egyptian Bronze Implements;" (3) J. G. Garson, Esq., M.D., "The Frankfurt Craniometrical Code." In consequence of the removal there will be no meeting on April 8th. The next meeting will be held at No. 3, Hanover Square, on Tuesday, April 22nd.

Royal Institution, 3 p.m.—Prof. Gamgee, "Animal Heat."

Royal Medical and Chirurgical Society, 8.30 p.m.—The following Papers will be read:—(1) E. Noble Smith, "Seventy Cases of Dupuytzen's Contraction of the Fingers;" (2) H. Radcliffe Crocker, M.D., M.R.C.P., "Three Cases of Xeroderma Pigmentosum (Kaposi)." The patients will be exhibited a second time, the morbid growths having been removed.

26. *Wednesday*.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Royal College of Physicians, 5 p.m.—Dr. Hughlings Jackson will deliver his Third Croonian Lecture "On Evolution and Dissolution of the Nervous System."

27. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Parkes Museum, 8 p.m.—Mr. Watson Cheyne will give a Demonstration "Of all the Principal Types of Micro-Organisms." Sir Joseph Lister, Bart., will take the Chair. Tickets for admission can be obtained through Members of the Museum.

Royal Institution, 3 p.m.—Prof. Tyndall, "The Older Electricity."

28. *Friday*.

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Clinical Society of London.—The following Papers will be read:—Dr. Finlay, "Cases of Enteric Fever, associated with Rheumatism;" Mr. Davies-Colley, "Case of Dislocation of the Spine;" Mr. Durham, "Case of Neuralgia successfully treated by Trephining;" Dr. de Havilland Hall, "Sequel to Case of Perichondritis of the Larynx."

Royal College of Physicians, 5 p.m.—Dr. James Andrew will deliver his First Lumleian Lecture "On the Ætiology of Phthisis."

Royal Institution, 9 p.m.—Prof. Osborne Reynolds, "The Two Manners of Motion of Water."

TERMS OF SUBSCRIPTION FROM JANUARY 5, 1884.

CROONIAN LECTURES ON EVOLUTION AND DISSOLUTION OF THE NERVOUS SYSTEM.

Delivered at the Royal College of Physicians,

By J. HUGHLINGS JACKSON, M.D., F.R.C.P., F.R.S.

Lecture I.—[Abstract.]

After introductory remarks, the lecturer said, "Beginning with evolution, and dealing only with the most conspicuous aspects of it, we say of it, that it is an ascending process of development in a particular order. We make three statements, which, although from three different standpoints, are about the very same thing: (1) Evolution is a passage from the most to the least organised, that is to say, from the lowest well organised centres, to the highest least organised centres; putting this otherwise, from centres comparatively well organised at birth up to those—the highest centres—which are continually organising through life. (2) Evolution is a passage from the most simple to the most complex, again from the lowest to the highest centres. (3) Evolution is a passage from the most automatic to the most voluntary. So that the conclusion come to is, that the highest centres, which are the climax of nervous evolution, and which make up the 'organ of mind,' or physical basis of consciousness, are the least organised, the most complex and the most voluntary."

So much for the positive process by which the nervous system is "put together"—Evolution. Now for the negative process, "the taking it to pieces"—Dissolution.

The process of dissolution being the reverse of evolution, just spoken of, little need be said about it here. It is a process of descending undevelopment, it is a "taking-to-pieces" in the order, from the least organised, from the most complex and most voluntary, *towards* the most organised, most simple, and most automatic. I have used the word *towards*, for if dissolution were up to, and inclusive of the most organised, &c., if, in other words, dissolution were total, the result would be death. I say nothing of total dissolution in these lectures. Dissolution being partial, the condition in every case of it is duplex. Evolution not being entirely reversed, some level of evolution is left. Hence the statement "to undergo dissolution" is rigidly the equivalent of the statement "to be reduced to a lower level of evolution."

After making a broad division into uniform and local dissolutions, and speaking briefly of the difference, the lecturer adduced examples of dissolution, admitting that he had selected the most illustrative cases.

1. Starting at the bottom of the nervous system, the first example is the commonest variety of progressive

muscular atrophy. We see here that atrophy begins in the most voluntary limb, the arm; it affects first the most voluntary part of that limb, the hand; and first of all, the most voluntary part of the hand; it then spreads to the trunk, in general to the more automatic parts.

2. Going a stage higher, we come to hemiplegia, owing to destruction of part of a plexus in the mid-region of the brain. Choosing the commonest variety of hemiplegia, we see that there is a loss of more or fewer of the most voluntary movements of one side of the body; we find that the arm, the more voluntary limb, suffers the more and longer; we find, too, that the most voluntary part of the face suffers the most.

3. The next illustration is paralysis agitans, which I believe to be a morbid affection of the cortex in the mid-region of the brain (middle motor centres). But apart from all speculation, this disease illustrates dissolution well. In most cases the tremor affects the arm first, and most often begins in the hand, and most often in the thumb and index finger.

4. Next we speak of epileptiform seizures, which are unquestionably owing to disease in the mid-region of the brain. Taking the commonest variety, we see that the spasm mostly begins in the arm, nearly always in the hand, and most frequently in the thumb or index finger.

5. The next illustration would be by paralyses after epileptiform seizures; in these cases—so far as I have observed—the paralysis affects those parts which have previously been most convulsed; if this observation be correct, nothing further need be said, for if the epileptiform seizure illustrates dissolution, then the paralysis which follows it, as its shadow, illustrates it too.

6. Chorea is a disease in which the limbs (the most voluntary parts) are affected more than the trunk, and the arms more than the legs. In this case the localisation of the disease has not been made out; symptomatically, it illustrates dissolution.

7. Aphasia.—This well illustrates the doctrine of dissolution, and in several ways. We consider a case of complete speechlessness. (*a*) There is loss of intellectual language, with persistence of emotional language; the patient cannot speak and cannot make signs, except of a very simple kind; yet, on the other hand, he smiles, frowns, varies the tones of his voice (he may be able to sing), and gesticulates as well as ever. (*b*) The frequent persistence of "Yes" and "No" in the case of patients who are otherwise entirely speechless is a fact of extreme significance. We see that the patient has lost all speech, with the exception of the two most automatic of all verbal utterances. He retains those two words (really prepositions), which stand on the border-ground of intellectual and emotional language. "Yes" and "No" are evidently most general, for they assent to or dissent from any statement whatever; in consequence of being frequently used they are of necessity highly organised, and as a further consequence they are highly automatic. (*c*) A more important, though not more significant, illustration is, that the patient who cannot get out a word in speech, nevertheless understands all that we say to him. Plainly this is loss of a most voluntary service of words, with persistence of a more automatic service of words. We get illustrations from small corners. (*d*) As regards the utterance "No," we find three degrees of service, yet a patient may use it emotionally only—most automatic service; another patient may also be able to reply with it—a less automatic, but still very automatic, service of it (here this is some real speech). There is a still higher use of it, which some patients have not got. A patient who can reply "No" to a question may be unable to *say* "No" when told to do so. (*e*) A patient who is speechless may be unable to put out his tongue when told to do so; that he knows what is wanted is sometimes shown, by his putting his fingers in his mouth to help out the organ. The organ serves well in all more automatic operations. Here is evidently a reduction to a more automatic condition: there is no movement of the tongue more voluntary than that of putting it out when told.

So far I have spoken of dissolution affecting one side of the nervous system on different levels. Coming to the highest centres we speak of uniform dissolutions—of cases in which all divisions of the centres are subject to the same evil influence. I choose some cases of insanity. In doing this I am taking up the most difficult of all nervous diseases. I grant that it is not possible to show, in detail, that they exemplify the principle of dissolution; but choosing simple cases we may show clearly that they illustrate it in general. I take a very commonplace example—"delirium," in acute non-cerebral disease. This, scientifically regarded, is a case of insanity. In this, as in all other cases of insanity, it is imperative to take equally into account, not only the dissolution, but the lower level of evolution that remains. The patient's condition is partly negative and partly positive. Negatively, he ceases to know that he is in hospital, and ceases to recognise persons about him. In other words, he is lost to his surroundings, or, in equivalent words, he is defectively conscious. We must not say that he does not know where he is, *because* he is defectively conscious; his not knowing where he is, is itself defect of consciousness. The negative mental state signifies, on the physical side, exhaustion, or loss of function somehow caused, of some highest nervous arrangements of his highest centres. We may conveniently say that it shows loss of function of the topmost layer of his highest centres. No one, of course, believes that the highest centres are in layers; but the supposition will simplify exposition. The other half of his condition is positive. Besides his *not* knowings, there are his *wrong* knowings. He imagines himself to be at home or at work, and acts, as far as practicable, as if he were; ceasing to recognise his nurse as a nurse, he takes her to be his wife. This, we may say, shows activity of the second layer of his highest nerve-centres, but which, now that the normal topmost is out of function, is the *then* highest layer; his delirium is the "survival of the fittest states" on his *then* highest evolutionary level. Plainly, he is reduced to a more automatic (or, we may say, more familiar) condition. Being negatively lost to his present "real" surroundings, positively he talks and acts as if adjusted to some former "ideal" surroundings.

It is to be understood that each is a different dissolution. All that is meant is, that each shows a reduction from the voluntary towards the automatic, in what the centre diseased represents. If we take extreme cases, the case of progressive muscular atrophy and the case of insanity (delirium in acute non-cerebral disease), we say that the two are alike, because in each there is reduction to a more automatic condition, and we say, too, that they are unlike since the parts of the nervous system morbidly affected are exceedingly different.

I have so far almost ignored the distinction between nervous states and mental states. Now, if the case of insanity be considered as a series of mental phonomena only, it would be absurd to compare, or even to contrast, it with progressive muscular atrophy, which is a series of physical phenomena only; but no difficulty can arise if it be understood that insanity or "disease of the mind" is, with medical men, disease of the highest nervous centres, revealing itself in a series of mental phenomena; we compare and contrast disease of the highest centres with disease of certain anterior horns (some lowest centres), revealing itself in atrophy of muscles. But, acknowledging this, it may be said that the two things are so exceedingly different, that it is frivolous to

compare or even to contrast them. Yet no one denies that each is a morbid affection of the central nervous system; this being granted, the rejoinder to those who insist on their extreme unlikeness is that the lesion in one is at the very bottom, in the other at the very top of the central nervous system; two lesions cannot possibly be farther apart in the central nervous system

I next speak of different depths of dissolution. The deeper the dissolution, the shallower the level of evolution remaining. I take in illustration some of the eight cases. Of hemiplegia, owing to lesion of the internal capsule, there are three degrees or depths (of course the division into three degrees is arbitrary). In the first degree there is some paralysis of the face, arm, and leg; in the second degree there is more paralysis of these parts, and in addition there is a greater range of paralysis — the patient's head and eyes are turned from the side paralysed. Here is illustrated what I call "compound order." The difference between the two degrees is not that in the second there is more paralysis only, nor that there is a greater range of paralysis only, but in both respects; there is more paralysis of the parts affected in the first degree, and extension of range of paralysis to parts beyond them. An adequate doctrine of localisation has to account for such increase of paralysis in compound order. Then in the third degree of, or rather beyond, hemiplegia there is universal immobility. In this condition the patient has lost consciousness, and this loss may be said to explain why he does not move the "other" or "second" side of his body; but this explanation is obviously verbal. I admit other difficulties.

I now speak of degrees of epileptiform seizures, as illustrating depths of dissolution. There are degrees of these, from spasm of the thumb and index finger to universal convulsion. That these degrees are compound is very evident. The first stage of the fit is, to speak roughly, that the arm is a little affected; the second stage is that the arm is more affected, and the face a little; the third stage is that the arm is most affected, the face much, and the leg a little.

Degrees of dissolution were illustrated by taking a larger range of cases of aphasia from slight defect of speech to entire loss of it. It was insisted on that in each case the symptomatic condition was double—that there was a negative and a positive element. To recognise this was particularly important in cases sometimes called "defect of speech;" the patients not saying what we call the right words was alone owing to the disease—the dissolution; his saying the wrong words was owing to activity of healthy nervous arrangements—to activity on the lower level of evolution remaining.

THE CRYPTOGAM GROUP.

A Students' Lecture.

By JONATHAN HUTCHINSON, F.R.S.,
Consulting Surgeon and Emeritus Professor of Clinical Surgery to the London Hospital.

Gentlemen,—It has been said that there are three hundred and sixty-five different diseases of the skin. You need not, however, be in the least discouraged by this suggested multiplicity of maladies, nor yet by the very numerous names which have been invented for them. A little industry and, if we can get it, a clear plan to begin with, will, I feel sure, make the successful study of skin diseases of great interest, and by no means difficult.

In the first place, you must get rid of the notion that these so-called diseases are really individual maladies, wholly separate and distinct from each other. They are no such thing. In nine cases out of ten, the names have been given to modifications of processes of disease, which are due to something peculiar in the patient's constitution. It is scarcely possible for us, when we are observing the varieties which disease presents, to make too much allowance for the inborn differences in different persons; and in the study of skin diseases, more, perhaps, than in any other subject, we have constantly to remember that it is not alone the influence which has been brought to bear from without, with which we are dealing, but the vital and structural peculiarities of the person upon whom these influences have been brought to bear. In many cases individual peculiarities may give a definite tendency to disease, as, for instance, when a strumous constitution is inherited, or that peculiarity of vascular organisation which gives a tendency to chilblains. In each of these cases the peculiarity of the person gives a direct and definite tendency to disease, and may be thus suitably be spoken of as its predisposing cause; or, if you prefer it, you may speak of the constitutional peculiarity as a diathesis. Thus, everything which is strumous is produced in part, at least, by the strumous diathesis or peculiarity in the individual, although as contributory, or perhaps what are known as exciting causes, injuries, defects in diet, exposure to hardships, and the like, may have taken important shares. We must never forget that diseases, as we see them, are seldom the result of a single cause; but that, commonly, there is a sort of partnership of various influences of which we witness the joint or compound result. Never let the fact, that a disease has received some special name, mislead you into forgetfulness that you have still to study and to recognise its causes. We study causes and their results, and in classifying diseases we ought to classify them in relation to cause and not to mere external or internal resemblances.

Even in cases in which the principal or direct cause of the malady may be supposed to be always of one and the same nature, we shall still witness, from differences in the constitution of the recipient, very remarkable variations in the result. The specific poison which, when introduced into the human organism, gives rise to the disease which we know as syphilis, is probably as special and specific in its nature as are the seeds of clover or wheat; but, although in essentials the results of its implantation are always the same, yet the limits of variation in severity and in external character are very wide indeed. In one person an eruption, it may be consisting of nothing more than a dozen little scaly spots, which never give him the slightest trouble, may be all that happens; whilst another almost dies with an eruption of ulcerating blebs which cover his whole skin. The difference is not in the poison, it is in its recipient. These differences in the individual are sometimes so strange, and render him liable to such very peculiar and almost outrageous manifestations of disease from apparently simple causes, that they pass quite out of the range of ordinary methods of explanation. Just as there are those to whom the very smallest quantity of mercury, opium, or belladonna acts as the most virulent poison, so are there others in whom the virus of syphilis or of varicella may produce results of the most exaggerated intensity. To rare conditions of extreme susceptibility of this kind we give the name of idiosyncrasy. In endeavouring to interpret the phenomena of skin disease, especially of its rare forms, I shall have constantly to remind you of the power of idiosyncrasy, and to ask you to believe that we are witnessing, not the effects of some new and very peculiar kind of cause, but simply the action of common causes in very peculiar individuals. No two persons are alike, and some, although in the enjoyment of, in the

main, excellent health, are still the subjects of peculiarities of organisation, which place them quite apart from almost all others. When a person cannot distinguish between the leaves of a cherry tree and its ripe fruit, excepting by their form, we say that he is "colour blind"; and we believe respecting this colour blindness that it must depend upon some undiscovered peculiarity in his retina or in his central centre of vision. It is convenient to give to such a condition, hypothetical, I admit, but still almost certainly present, the name structural idiosyncrasy. You will see that we mean by idiosyncrasy something far more exceptional and abruptly marked than those conditions which we should name structural peculiarities. The difference is, however, in degree only; idiosyncrasy is merely personal peculiarity in its intensest form. When we see a face covered with acne spots, we know that in all probability there exists in that individual, as a personal peculiarity, a large development of the sebaceous glandular system. And some forms of acne may be said to be possible only to those who possess, as matter of original endowment, thick, coarse skins. To conditions, however, which are so common as these, we should not think of applying the term idiosyncrasy.

I have spoken thus in detail as to the importance of remembering the possible existence of personal peculiarities, because I feel sure that, unless we do so, we shall constantly encounter problems for which there is no possible solution, and shall be naming as diseases, and thinking of them as if they were in some way complete in themselves, conditions which have no business whatever to take such rank, but which result simply from the action of everyday influences upon persons who have inherited special peculiarities of function or of structure.

It may be well, perhaps, next to say a few words as to the anatomy of the skin itself as modifying the conditions of disease. You must try and get into the habit of thinking of the skin by the aid of the microscope. You must constantly remember that it is a very complex organ, possessing great elaboration of structure, and including in its substance an immense number of microscopic viscera, which may, at any time, become actively engaged in the production of disease. A papilla, or a group of papillæ, may take on a tendency to overgrowth, a sebaceous gland may become choked by its own secretion. A nerve corpuscle may become hyperæsthetic, or a leash of nerve filaments may suffer neuritis. I mention only a few of the possibilities in the way of variety of structural disease which may happen in the skin. You must be constantly forcing the mind to take cognisance of the actual existence, in each little portion of skin, of these varieties of structure; and constantly asking yourselves, when looking at a portion of skin in a state of disease, which of its special structures it is which is mainly involved. I must leave you to master this anatomical knowledge for yourselves; but let me impress upon you that it is of extreme importance.

According to the classification which I have proposed, that is, grouping skin diseases in relation to their causes, or at any rate (so far as we can discern them) in relation to their natural affinities, we will now proceed to describe them in their several families. The one which I think should be mentioned first, on account of the simplicity and sameness of its cause, is that which is due to the invasion of vegetable parasites. We have under this head, a little group of maladies which are very definite in their nature; they are modified to some slight extent by the age of the patient, and by the peculiarities of his tissues, but scarcely, if at all, by his state of health. They occur to the robust as well as to the feeble, and they are not to be cured, not even, perhaps, in any material degree influenced, by internal remedies or by diet. They are from beginning to end local, induced by local contagion, and to be cured by local medication. If ringworm gets into a school, it will, unless special precautions be taken, affect every child in it, and will run its course in each without any material modification from different states of general health. We may take Ringworm as the type malady of this group, for it is by far the most common. It is caused by the implantation of a fungus which consists of spores and jointed threads, which grow in the epidermis, in the lining membrane of the hair follicles, and which flourish with the greatest vigour in the hairs themselves, especially in the soft succulent hairs of young children. The presence of this fungus is revealed by the brittleness of the hair, which results in a breaking off of the hairs at a short distance from the scalp; leaving a patch which is not actually bald, but is covered only by the broken stumps of hairs, and by bran-like scales of epidermis. If you have once seen a ringworm patch, you can never again mistake it, if at all well characterised. The patches are almost always round, unless made irregular by the coalescence of two or more at their margins; and the stumps of the hairs upon them have lost their lustre, and look like broken tow.

It is not at all always that ringworm is well characterised, nor is it the same in its features in all stages of the same case. Sometimes the rings are ill marked, and only a few of the hairs break, and in these the chief feature to be noticed is the accumulation of epidermic scales. Without the aid of the microscope these cases cannot be distinguished from common pityriasis. By the help of the microscope, however, the diagnosis is almost always easy, you have but to put the hairs or epidermis upon a slide with glycerine or liquor potassæ, and the demonstration of the presence of spores and mycelum will place the matter beyond all doubt. Although I have denied that the general health exercises any material influence on ringworm, yet it is to be admitted that personal peculiarities do so. Children of black, strong, hard hairs suffer much less from it than others, and it is a well-known fact that at a certain age the hairs cease to be liable to its attacks. It cannot be said that the liability to ringworm ceases, for in adults, at all periods of life, we occasionally see this affection, but the fungus confines itself to the epidermis, and does not grow in the hair, and it flourishes only on certain parts of the body, whilst it avoids the scalp. These parts are for the most part the armpits and the regions adjacent to the perinæum; here it covers large well-margined areas, which look more like eczema than they do like common ringworm of the scalp, and which have from that feature got the name of eczema marginatum; the fungus is, however, that of common ringworm, and there can be no doubt as to the identity of the disease. A lady consulted me on account of an eruption on the labia and thighs, from which she had suffered for a year. I noticed that it was abruptly margined; on examination with the microscope found plenty of fungus; she told me that it had begun whilst she had been engaged in dressing her daughter's head for ringworm.

The skin disease in closest alliance with ringworm is that named Chloasma or liver spots, or pityriasis versicolor, or, best of all, tinea versicolor. In this disease we have abruptly margined yellowish brown patches, developed for the most part symmetrically on the chest, abdomen, back, and upper parts of arms. The patches are but very slightly scaly, and their peculiar colour is their principal feature. On account of it they are very frequently mistaken for syphilis. You are aware that Sidney Smith avowed his belief that blue-coat boys turned into quakers, alleging that he had never seen a quaker boy or a blue-coat man, and that precisely at the age when the one ceased to appear the other began. Now ringworm and pityriasis versicolor

stand in the same relation to one another, we never see the one in children, and we never see the typical form of the other in adults; ringworm is very rarely witnessed later than the age of fourteen or fifteen, and exactly at this point of life do young people become liable to chloasma. I suspect, however, that the relationship is not only seeming, but real; and that although the two diseases look very different, they really depend on altered forms of the same fungus. Over and over again I have known nursemaids who had the care of children suffering from ringworm develop chloasma on the chest. I show you here a drawing of some patches which I produced when a student on my own chest by the contagion of scales from a child with ringworm. In certain minor features the cryptogam in the two cases differs in its mode of growth, but I have really no doubt as to the possibility of its transmutation, and practically, therefore, of their identity. The age of liability as to chloasma, as well as ringworm, is limited; it develops freely in adults, but is rarely seen after middle life. Several conditions certainly render the skin much more susceptible. It prefers the parts which are covered by the flannel vest, and but seldom extends beyond them; those who sleep in their vests, and who use soap and water sparingly, are the most liable to be affected by it. But when once it is well established, cleanliness will certainly not cure it. I have been told that in Norway, where woollen is universally worn next the skin, and where, among certain classes, it is the custom not to change it for many weeks together, chloasma is exceedingly common. To make the microscopic diagnosis of chloasma, you have but to scrape with your pen-knife the epidermis from a patch. It is curable, with the greatest ease, by immersion of the body in a sulphur bath, or by the use of any one of the numerous lotions which destroy vegetable parasites.

I have kept the most interesting of the cryptogamic skin diseases to mention last. Being a rarity, it is in some respects of less practical interest to you than those of which we have just spoken; in severity, however, it far exceeds them, and your interest in it may be increased by remembering the fact that if you fail to cure it in an early stage, it will torment its victim through his whole life. When I was a student at the York County Hospital, I saw my first case of favus—a man who had then been in many workhouses and many jails, whose scalp was almost bald and covered with favus crusts. He had had the disease from early childhood: it had prevented his attending school, and hindered him from obtaining occupation. The odour of mice was so strong and loathsome that no one would willingly associate with him. At different periods, ten or fifteen years later, at St. Bartholomew's Hospital, and at the Hospital for Skin Diseases, I met this same man, and the poor fellow was still uncured of his favus. Every hospital sent him out well after a few weeks of treatment, but the cure never lasted more than a month.

The facts respecting favus are briefly these. Like ringworm and chloasma, it is produced solely by contagion, by the implantation of a fungus on the skin of a previously healthy child, although it may continue on, as we have just seen, into adult periods; yet, like ringworm, it begins almost without exception in childhood. Its fungus can grow on the naked skin as well as on the scalp; but, like ringworm, it is usually easy of cure on all other parts but the scalp. The explanation of this is the same in both cases, that the fungus hides itself in the deep follicles of the large scalp hairs, and there escapes the influence of the parasiticide applications which you employ. Favus differs much from ringworm in its external appearances; instead of producing simply a breaking up of the hair and epidermis, attended with slight shedding of epidermic scales, it grows into thick masses of fungus material upon the surface of the skin. These masses may be a quarter of an inch or more in thickness, and although at first they may take the form of cups, from being developed in hair follicles, yet by the coalescence of these cups great irregular masses of crust may be produced, which may cover almost the whole scalp. Not only may they cover the scalp, but in neglected cases they may cover the whole body. There is, I believe, in the Museum of St. Thomas's Hospital the portion of the skin of a boy who died of favus, which involved almost the entire surface. Such extension, however, cannot happen unless the patient has been grossly neglected. These favus crusts are peculiar, and resemble nothing else; they do not consist of pus, nor of epidermis, and they are not in the least sticky. If you take a little, and rub it between the fingers, it will break up like so much half-dried putty. Their colour is yellow, and they have a disgusting odour—that of a cupboard which mice have frequented. I have made the diagnosis of favus by the odour alone within a few minutes of a patient entering a room amidst a crowd of others. Some, however, smell but little, and it is to be noted that mice vary very much as regards this particular odour, and that mice are liable to favus, and not unfrequently die of it. I have seen a poor mouse encrusted with favus from mouth to tail until it could scarcely move. Possibly, when the odour of mice is unusually bad, it is because some of the colony are suffering from this disease. I have known several cases in which there seemed good reason to believe that children had contracted favus from mice. I have known many in which no doubt could be entertained of its having spread from child to child. Inoculation experiments, performed by students upon themselves, have also repeatedly succeeded. Thus there can be no doubt that favus is contagious, and that it spreads solely by contagion. But, at the same time, it is to be noted that it does not spread easily. It is like a plant which is difficult of propagation, but which flourishes well when once it has taken root. The difficulty of transmission explains its rarity—if it were as easy of contagion it would be far more common than ringworm, for it is far more difficult of cure, and therefore more protracted. Possibly the friability and non-adhesive quality of its crust explain the rarity of its transmission from one subject to another. Be this as it may, you must not expect in English practice to see more than three or more cases of favus in the course of your lives.

In France it is far more common. With us it is a disease which affects only the very poorest and most neglected. There has been some debate as to whether favus is in any sense scrofulous, or in connection with low health. I feel sure that it is not so in the least, having seen it more than once affecting a whole family of children of sound constitution. When severe, it induces ill-health, and causes chronic enlargement of the glands, and thus it is easy to make a mistake between effect and cause. And now a few words as to treatment of this really terrible malady. If you make the diagnosis correctly when it is just beginning, there is no difficulty in stamping it out. You must clear away the crusts, and apply a parasiticide, or if the patch be on the scalp, I am not sure it would not be wise to cauterise with nitric acid; on other parts this is not necessary. If the patch be small, and on the naked skin, it is got rid of very easily. I once admitted a child into this hospital with a group of three or four beautiful crusts of favus newly formed on the side of its chest. I intended at my next visit to demonstrate the case and give a lecture on the disease, but the nurse considered it a matter of cleanliness to clear away the cups, and when the time for the lecture came there was nothing to be seen. I believe we used

*

nothing more than a little ammonio-chloride ointment, and no favus ever grew again.

The cryptogam of favus, being exceedingly abundant, is demonstrated with the greatest ease. Its spores and threads are much larger than are those in ringworm and chloasma. I ought to have told you, in speaking of ringworm, that it occasionally affects the nails: the same is also true of favus. In ringworm the growth takes place in the nail substance, which it splits up and renders opaque and fibrous; but in favus the growth is under the nail, which becomes lifted up by a mass like yellow putty. Both affections are rare; I have myself seen but a few cases of ringworm in the nail, and only one of favus.

With these three diseases, ringworm, chloasma, and favus, we finish our list of the cryptogamic affections of the human skin. Let me repeat that they are all contagious, and spread by contagion only, and are quite incapable of spontaneous development. Let me also emphatically state my belief, that none of them require any predisposing conditions, excepting youth. In all of them the first beginning of the growth is at a point, and from this point the fungus spread out at its edge, until a rounded area is involved. In ringworm only is there any tendency to the formation of rings, and in it, in spite of the name, this condition is exceptional; patches, not rings, are its ordinary condition. It is convenient to have one name for the whole family, and the name which has been adopted is that of *tinea*. Tinea favosa, or lupinosa, means favus. Tinea versicolor denotes chloasma; and tinea tonsurans, ringworm. But employing the word tinea with this signification, we must get out of the habit of speaking of tinea tarsi, for the chronic inflammation of the roots of the eyelids—to which this latter name was formerly applied—has nothing to do with the presence of a cryptogam. Let the term tinea be wholly restricted to diseases which we believe to have been solely and wholly caused by the growth of a vegetable mould on the skin. Very interesting botanical questions arise as to the relationship and differences of the cryptogam present in these several diseases. But upon these I must not enter. We distinguish them under the microscope by the size of the threads and spores, and by the arrangement of the latter. But it is, as I have already hinted, by no means certain that they are not varying forms of the same fungus. They have received, however, different names, and by these we must know them. Professor Schönlein, the discoverer of the cryptogam in favus, has been honoured by having the fungus named after him the "Achorion Schönleinii." That of chloasma is named "Microsporon Furfurans," and that of ringworm, "Trichophyton Tonsurans."

Before we leave the subject of the vegetable parasites which flourish on the skin, it may be well that we should give our attention to another malady, respecting which it is yet doubtful, whether or not it ought to be classed with them. In many features it resembles ringworm; but its patches are not branny and covered with the stumps of tow-like hair, but are perfectly bald, white, glossy, and smooth. Like those of ringworm, however, they begin at a point and spread out at their edges, and produce round coin-like patches, which by coalescence may constitute great areas of irregular shape. It has been named hastily, tinea areata, or, more wisely, alopecia areata. The latter name involves no theory of cause, but simply states that baldness occurs, not difusely, as in the senile form, but in abruptly margined areas. It is exceedingly difficult to believe otherwise than that these round patches of baldness scattered about the scalp, and spreading at their edges, are due to some local cause; and usually there is nothing whatever in the state of the patient's health to suggest any other theory. Alopecia areata, or area, occurs, like ringworm, usually to young people, though by no means restricted to children. It comprises the period of life during which both ringworm and chloasma occur. It is extremely rare to see it begin after middle age. The reason for hesitating to place it by the side of ringworm, is that in ninety-nine cases of the hundred it is impossible to demonstrate the presence of any fungus by the microscope. The affected hairs wither at their bulbs, and then fall out; but neither in the shrunken bulb, nor in any part of the shaft, can you, as a rule, detect any fungus; nor is any to be found by scraping up the epidermis, or blistering the patch. The disease further differs from ringworm in that it is almost incapable of spreading by contagion. You may let a patient with alopecia areata go to a boarding school, and it is a hundred to one that nothing will occur to make you regret it. This non-contagiousness is, however, not absolutely without its exceptions, nor is the absence of fungus. Now and then you will see the disease apparently spread by contagion, and now and then microscopic observers will discover a fungus, which, excepting in size, differs but little from that of ringworm. There are other curious facts which seem to connect the two maladies. Thus, it is common for alopecia areata to occur on the scalps of young adults, who had in childhood suffered from ringworm, and this may happen after an interval of ten, fifteen or twenty years. In my own practice it has certainly been the rule, rather than the exception, to receive this history. Then, again, it is by no means uncommon to see cases in which the conditions of alopecia and ringworm are mixed, or in which one child suffers from ringworm, and another, probably an older one, shows the characteristic conditions of the other disease. I confess that I cannot shake my mind clear of the seeming lesson of these facts, and despite the absence, for the present, in the vast majority of cases of any microscopic proof, I suspect that alopecia areata is a true tinea. The impossibility of discovering any other cause, and the fact that its subjects are generally in excellent health, seem to add plausibility to this hypothesis. It may be that the fungus grows only in the deeper layers of the skin, and thus eludes observation. We are bound, however, for the present to admit that we have no real knowledge as to the nature of this malady. It is a very troublesome and annoying one, and often happens just at the age when its ravages are the most vexatious to its victim. I have seen a young lady in splendid health, and in all other respects well fitted for the full enjoyment of life, burst into tears as she took off her wig, and disclose the fact that she had not a single hair on her scalp; and I have known members of the other sex, who were chagrined almost beyond endurance by the disappearance in succession of scalp, hair, beard, whiskers, eye-brows, and eye-lashes. The fact that it is not attended by any failure of health seems to make it the more annoying.

Leaving, then, as we must, in utter doubt, the question as to the true pathology of alopecia, there are yet a few facts which must be stated as to its clinical history. It is very rare in young children, but about the age of ten it begins to get common. It now and then occurs in the course of syphilis. But this may be easily a mere coincidence. It usually begins on the scalp, but in men it is not uncommon for it to attack first the beard or whisker. A single isolated patch is usually first discovered, but after a while many other patches, it may be at a considerable distance from each other, make their appearance. Sometimes it extends over the whole body, and denudes the patient to his last hair. The eye-lashes are usually the last to fall; and, if recovery takes place, the first to come back again. When it extends over the body, it does so still in the form of patches, which spread at their edges; there is never, or scarcely ever, any diffuse thinning of the hair to be observed. It is not difficult by the use of blistering or

the use of irritating ointments to make the hair grow again. But even after a luxuriant crop has been produced, and retained for months or even years, a recurrence of the alopecia may happen. All these facts seem to my mind to point to a local cryptogamic origin. It is possible, though not very probable, that there are different forms of the disease, and that some are local and others not so. You must remember that the baldness which follows fever, and other states attended with great debility, is always a diffuse thinning, and never assumes the areate character. Ringworm is often observed in the lower animals, especially in calves; but I am not sure that alopecia areata is ever witnessed in them. In one case, however, in a calf whose portrait I now show you, the patches of baldness were not in the least like those of ringworm, but were exactly those of area.

CLINICAL LECTURE ON THE OPHTHALMIA EPIDEMIC IN GREENOCK.

By J. R. WOLFE, M.D., F.R.S.E.,

Surgeon to the Glasgow Ophthalmic Institution, Lecturer on Ophthalmology in Anderson's College.

Since July, 1883, a number of cases of conjunctivitis from Greenock have applied at this institution for treatment. They were all of a severe form, tending to involve the tarsi, cornea, iris and deep structures. As they were all of that pernicious type, I called your attention to the fact, expressing my apprehension that Egyptian ophthalmia must be prevailing in that locality; for, indeed, we seldom meet with a succession of such severe cases in this country. The form with which we usually have to deal is trachoma, that is the existence of granulations consisting of sago granules which generally take months or years to develop. They are associated with pannus—superficial vascular inflammation of the cornea leading to gradual degeneration of the corneal epithelium, and afterwards of the anterior elastic layer, and in progress of years, the tarsi become affected, giving rise to entropion. These conditions are of slow and insidious development. Suppuration, when it does occur, is scanty.

The cases just alluded to were at the initial stage, accompanied by profuse suppuration and hypertrophy of the papillæ with furrows in the conjunctivæ palpebrarum in which pus lodged, the cornea suppurated very rapidly, the iris in some cases adhered to the lens capsule. Another remarkable feature was, that the upper lids, instead of being inverted, were on the contrary inclined to eversion, presenting a slight degree of lagophthalmos, owing to the great swelling at the conjunctival *cul-de-sac*, and the distension of the lids. At the first glance this might have been mistaken for gonorrhœal inoculation, and from the outer aspect of the eye for diphtheritic conjunctivitis, for the upper eyelids were œdematous, distended and glistening. But the absence of diphtheritic patches, the nature of the discharge, and also the fact that both eyes were affected at the same time, as well as several members of a family attacked simultaneously and in both eyes, precluded the idea of gonorrhœal inoculation. The *ensemble* of the symptoms justified our apprehension of the serious nature of the epidemic. At last I was asked to see the ophthalmic surgeon of the Greenock Infirmary, who had himself unfortunately become a victim of the affection. There was in his case œdema of the lids and hypertrophy of the papillæ, while the conjunctivæ of the lids presented several sulci, within which was lodged purulent string-form discharge. The iris of the left eye had become slightly implicated. In this condition he had been for two months previous to my visit.

The cases which came under our notice here from Greenock, and for the report of which I am indebted to Dr. A. T. Thomson, were as follows:—

Case I.—V. L., aged 35 years, blacksmith, applied on the 21st July with purulent conjunctivitis of both eyes, œdema of the lids and conjunctivæ, and hypertrophy of the papillæ, which had existed for some months previous. In the left eye had commenced the formation of sago granules.

Case II.—C. D., aged 22 years, went into the Greenock Infirmary for injury of the right eye. He became infected, and when he applied here on the 20th September there was present trachomatous pannus, and degeneration of the cornea, and notwithstanding removal of the injured eye, shrinking took place. He was dismissed incurable.

Case III.—R. P., aged 31 years, police-constable, applied for treatment here on October 3rd, with chronic conjunctivitis and extensive granulations in the lids of both eyes. Complained of great pain in the supra-orbital region. There was considerable lachrymation, with intolerance of light, a sensation of sand or grit in the eyes, and swelling of the lids at their edges.

Case IV.—J. R., aged 2 years, was brought here for treatment on October 3rd, on examination it was found that the right eye was lost, and the left in considerable danger. There was profuse suppuration, and swelling of the eyelids; the eyelids were so swollen and heavy that the child could not raise them unaided. You noticed the rapid change towards recovery which, by means of the treatment adopted, took place a few days after admission, and continued until the patient was discharged cured, with the one eye.

Case V.—H. R., aged 50 years, policeman, applied for treatment on 29th October. He suffered from granular lids with central opacity of the cornea, and anterior adhesions in the left eye. It is worthy of note that Case III. lodged with this patient, who became infected through contact.

Case VI. — J. A., aged 14 years, sailmaker, applied here for treatment on November 2nd. There was present deep ulceration of the right cornea, and superficial ulceration in the left. There was profuse suppuration and enormous œdema of the eyelids. Extensive furrows of the conjunctivæ palpebrarum were noticed, when the lids were raised, with a copious discharge of greenish yellow pus, there was so much ecchymosis that the corneæ were deeply buried in the swollen conjunctivæ. There was total inability to raise the lids. Rapid improvement took place, and you observe that now there remains only a slight degree of chronic conjunctivitis.[1]

Case VII.—M. C., aged 7 years, applied here on November 16th for treatment. Both corneæ were in a state of deep ulceration, which, however, did not progress so far as to cause perforation. The conjunctival suppuration was profuse. You noticed the amount of blepharo-spasm which we had to deal with in this case. The patient rapidly improved and recovery took place, leaving behind, however, a slight opacity of the corneæ.

Case VIII.—A. C., aged 5 years, was brought here for treatment on November 16th, with granular conjunctivitis, with the characteristic sago granules. There was a general haze over the corneæ, with copious purulent discharge.

Case IX.—Mrs. C., aged 29 years, mother of the above, suffered from chronic conjunctivitis, the result of inoculation from her child. There was in her case

[1] This patient presented himself again on February 14th, and although the conjunctival swelling has greatly disappeared, there still remains a slight eversion of the lids.

also suppuration with œdema of the lids, which, however, rapidly disappeared under treatment.[2]

Case X.—M. F., aged 3 years, was brought here for treatment on December 1st. She suffered from profuse suppuration in both eyes. The corneæ were almost out of sight, from the overlapping swollen conjunctivæ, eyelids very œdematous, which when raised allowed the pent-up pus to gush out. This case also made a most rapid recovery, and was dismissed cured.

Case XI.—Mrs. G., aged 35 years, came here for treatment on December 2nd, with granular conjunctivitis of a pronounced form. There were extensive furrows in the conjunctivæ, in which pus was lodged. Improvement began to take place after a fortnight's treatment, and she was ultimately dismissed cured.

Case XII.—J. McJ., aged 67 years, applied here for treatment on December 19th, with suppurative conjunctivitis, similar to Case III., which improved under treatment, and was ultimately discharged cured.

While in Greenock I visited the Infirmary to see the hygienic condition of that place. I found a mother and two children labouring under the same affection, all of them presenting œdema of the eyelids, with slight eversion, profuse suppuration, and in the case of the mother the corneæ were opaque. In one of the children the cornea of one eye was sloughing, and in the other child, although the corneæ had so far escaped, the iris had begun to adhere. This family may be considered as presenting a type of the epidemic, namely, profuse suppuration of the conjunctivæ of both eyes, œdema of the eyelids, with the upper lids hanging over the eye-balls and slightly everted, and a tendency to sloughing of the cornea, and adhesion of the iris. In the majority of cases there is no time for the formation of sago granules. This neoplasm, or inflammatory product, is only formed in a chronic and long-protracted process, or, indeed, they may be considered as a residuum of the affection.

Origin of the Epidemic.—On account of the virulent type of the cases which came under our notice, I directed the attention of the Provost of Greenock to the epidemic, stating that the disease had probably been introduced by sailors or soldiers returning from Egypt. In examining also the sanitary condition of the infirmary I thought it incumbent on me to add that I had long been of opinion that country hospitals were not suitable for the treatment of eye diseases, and that my inspection of the Greenock Infirmary had satisfied me that it was no exception to the rule. When it can possible be had, a separate hospital for this department is always desirable, or, at least, a separate wing ought to be devoted to it, in towns in which it is wished to preserve a close connection between it and the general infirmary. I thought this statement the more necessary, because public bodies are proverbially dilatory in dealing with such questions. I had the satisfaction of receiving the thanks of the Provost for having publicly called attention to that circumstance, as public opinion will enable the authorities to overcome existing difficulties and take active steps in putting the ophthalmic department of that hospital on a satisfactory footing.

Treatment. I.—The course of treatment which we have adopted was regulated by the circumstances of each case. During the suppurating stage we recommended warm poultices during the first 24 hours, also a collyrium boracis to wash out the whole of the conjunctival sac, and when we found this to be insufficient for the moderation of the purulent discharge, the mitigated nitrate of silver, in solid form, and the solution of atropine were substituted, and the case treated as an ordinary one of blenorrhagia. The application was repeated every day, or every second day, according to circumstances.

II.—In cases of hypertrophy of the papillæ the conjunctivæ palpebrarum were scarified freely, and then fomented with warm water in order to encourage bleeding, then syrup of tannin was applied to the surface.

III.—When sago granules had already appeared, they were removed by friction, as in cases of trachoma. Constitutional treatment, nourishing food, and mild laxatives, plenty of open air exercise when the weather permitted.

IV.—We took the precaution to have all these cases isolated, being strongly of opinion that quarantine, proper ventilation, and cleanliness are essential to the eradication of the disease. Warm baths twice a week were also ordered.

The authorities of the Greenock Infirmary have carried out my recommendation with regard to clearing the hospital wards of all the eye cases, and procuring temporary accommodation elsewhere for the indoor patients.

[2] This patient was seen on February 29th, with slight conjunctival redness.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

BRADFORD INFIRMARY.

STATISTICS OF AMPUTATIONS DURING FIFTEEN YEARS, ENDING 1883.

By WM. JAS. SPENCE,
House Surgeon.

In recording the results of amputations performed at this institution during the past fifteen years, I have been unable to give the percentage of deaths under the separate headings (primary, secondary, and for disease). This detracts from their value considerably; but, even with this omission, I think the totals will be sufficiently interesting to warrant publication.

Statistics of operation, like the following, can only be an approximation to the truth; so many accidents, which it is impossible to represent in tables, have a determining influence in the ultimate success of the cases. Take, for example, the fatal case of amputation of shoulder joint—the patient was severely injured about the thorax, his ribs being driven in, this set up inflammation, which resulted in suppuration and ultimate death. Had the injury to the arm, which necessitated the amputation, been the only one, in all probability the patient would have recovered. Many of the primary amputations are on patients suffering from multiple injuries, many of them in themselves sufficient to cause death, independently of the operation.

The success of secondary operations also often depends upon influences extraneous to the disease, or, at any rate, the local manifestations of it which determined the operation. The amputation of foot, the cause of death which is put down as due to tubercular disease, had almost recovered from the operation—the stump was almost healed—when pulmonary complication carried off the patient. These all tend to show that the results greatly depend upon the particular case, or class of cases, which the surgeon has to deal with.

I do not propose to enter into the question of treatment as affecting results. I myself am in favour of Listerism, and it is a significant fact that there has

been no death from erysipelas or pyæmia during the past three years, when amputations have nearly all been treated antiseptically.

The death-rate from amputation of leg, compared with that of other parts, is high; I can only account for this by the supposition that the class of cases has been unfavourable for operations. The more serious operation of amputation of thigh has been remarkably successful.

During the fifteen years ending 1874, there were fifteen double amputations for accident at Guy's Hospital, of which only two recovered. The same operation here has been much more successful—there have been four recoveries out of seven cases. The fatal cases were amputations of both legs; the recoveries were leg and thigh (two), both legs, and leg and arm. Taken as a whole, the death-rate, compared with other hospitals, is an exceedingly low one.

Amputations performed upon in-patients at the Bradford Infirmary during the past fifteen years.

Amputations.	Total.	Primary.	Secondary.	For Disease.	Result.		Death-rate per cent.
					Recovered.	Died.	
Of fingers and parts of hands	194	151	9	34	190	4	2·01
Of hand	11	8	1	2	11	–	–
Of fore-arm	36	27	1	8	35	1	2·77
Of arm	74	56	8	10	65	9	12·16
At shoulder joint ..	3	2	–	1	2	1	33·33
Of toes and parts of foot	50	25	3	22	49	1	2
Of foot	51	2	2	47	46	5	9·80
Of leg..	80	36	12	32	62	18	22·5
Of thigh	89	29	5	55	75	14	15·73
Totals	588	336	41	211	535	53	9·01

Of the four deaths tabulated under amputation of "fingers and parts of hand," two were due to erysipelas, one to pyæmia, and one to pleuro-pneumonia. The eleven amputations of hand were all successful. The death after amputation of fore-arm was due to pyæmia. Three of the fatal cases, after amputation of arm, were due to pyæmia, two to shock, and one to abscess of lung in connection with fractured ribs. The fatal case of amputation at shoulder joint was complicated with wound of lung and emphysema. The death under amputation of "toes and parts of foot" was the result of pyæmia. Of the five deaths after amputation of foot, two were due to gangrene, one to tubercular disease, and one whilst under chloroform.

It will be seen that there were eighteen deaths after amputation of leg (an unusual number compared with the deaths after amputation of other parts). Of these, two died from pyæmia (one a double amputation), three from gangrene, two from shock (both double primaries), one from tetanus, and one from tubercular disease.

Six of the amputations were primary and double, three of which died, and three recovered. There has been no death from erysipelas or pyæmia for three years.

Lotion in Severe Contusions. — Dr. Hewson, who resides in a town of Texas, where accidents from saw mills and lumber works are frequent, communicates to the *Philadelphia Medical News*, February 23rd, the formula of a lotion, which he says he has found of great utility in treating the severest contusions:—℞ Sodæ Hyposulphit. ʒiv, Acid Carbol. Cryst. ʒss, Glycerin. ʒij, Aquæ Oj. A cloth well saturated in the solution to be kept constantly applied to the part.

Medical Times and Gazette.

SATURDAY, MARCH 29, 1884.

The Government Medical Bill passed through Committee in the House of Lords, on Thursday se'nnight, without any opposition, and after criticism of only the very mildest and most courteous character. Lord Balfour, of Burleigh, and the Duke of Richmond warned the Government that the Scottish Universities are still dissatisfied with the measure; they still protest strongly against their alumni being obliged to pass the final examination of the Medical Board, as well as the final examinations for graduation; and they consider that arrangement unworkable and inexpedient. The two noble lords also stated, that there is a feeling in Scotland that an undue preponderance has been given by the Bill to Edinburgh and the Edinburgh schools; and they predicted that the measure would meet with much opposition and hostile criticism in the House of Commons. Neither of them, however, suggested or proposed any specific amendments; and the Duke of Richmond strongly urged the Government to use, in the interests of the public and the profession, every effort to pass the Bill this Session, observing, that if the Government were really in earnest about the matter, they ought to find no great difficulty in passing it before many of the measures now before the country.

Lord Carlingford, in reply to this appeal, said he should be deeply disappointed if the Bill was not carried this Session; and that he also felt very strongly that it was the duty of the Goverment to take every means in their power to secure that result; but he did not venture to state that the Government as a body take that view. In Committee he proposed and carried an amendment altering somewhat the constitution of the Medical Board for Ireland. In recognition of the force and justice of a remonstrance from the King and Queen's College of Physicians in Ireland, an additional representative on the Board is given to that body, thereby restoring to it the position given it by the Bill of 1883, and making its representation equal to that of the Royal College of Surgeons in Ireland, each body electing three representatives. Then, as that change made the voting power of the Corporations equal to that of the Universities and the Board, the latter bodies also are given one more representative, to be elected by the University of Dublin and the Royal University of Ireland collectively. The Universities will thus have seven representatives on the Board, and the Corporations six. This method of "allocating" representatives seems to be a favourite device with the Government; but it does not appear to have met with much favour in Scotland; and it may be doubted whether such patchwork will please the Irish authorities any better At the instance of Lord Carlingford also the following sub-section was added, as an offering, we suppose, to the great fetish uniformity, to Clause

19, which imposes upon the Medical Boards the duty of regulating a course of medical education, and the preliminary and previous examinations, viz., "Any scheme under this section shall be passed in such manner as to secure, so far as is practicable, between the several parts of the United Kingdom, a substantial equality of standard as respects education and examinations." This task will, however, present no difficulties to Medical Boards competent to frame, as the Boards are bound to frame for the final examinations, schemes that shall secure, as far as possible, in each division of the Kingdom, not only an equality of standard, but also "an equality of capacity for testing proficiency!"

The Report of Amendments on the Bill was received and agreed to in the Upper House on Thursday the 27th, and the Bill now goes to the Lower House, when it may again lie blocked till the end of the Session; or, should it escape that fate, will meet with much rough handling. The cry for "direct representatives" on the Medical Council having been granted by the Bill, attention is now called to the "humiliating position" in which these representatives, in common with the Crown nominees, are placed in being relegated to the Medical Council only; and a demand is made that they shall have seats on the Medical Boards also. Oliver Twist will always be with us; that classical type will never cease out of the land. But all who really desire an end to the wearisome and injurious agitation for medical reform, and are, therefore, ready to accept even an imperfect measure, should remember that a very little determined opposition will deprive the present Bill of all chance of becoming law. This will certainly not be forgotten by any of those who object to the Bill as doing more than is really needed, but we would express the sincere hope that such opposition will be conspicuous by its absence.

The debate in the House of Commons on recruiting last week exhibited a wonderful confusion of opinion. "The Colonels" were convinced that England had no army at all, and declared that a company of old soldiers of the type that served twenty-five years ago, would march through a regiment of the present day! Lord Hartington pointed with pride to the conduct of one young soldier in the Soudan, and other legislators quoted the opinions of the Duke and Lord Wolseley, who said different things at different times and places! Luckily, as medical men, we are not called upon to estimate the value of these opinions, but there are a few *facts* which may be usefully noted. As a matter of fact, Lord Hartington had to complain last year of a deficiency of numbers; but he boasts this year of having adopted *measures* which have procured the largest number of recruits ever enlisted in time of peace. We can guess at some of these measures, when we find that recruits *can* be taken between five feet four and five feet five, who are not required to weigh more than 120 lbs. A youth of these modest proportions would have to carry in war time a load of 51 lb. 1 oz., and at the end of a day's march might find himself face to face with a man of thirty, weighing between eleven and twelve stone, and averaging five feet eight inches in height.

We do not venture for a moment to express any opinion upon the point. If the doctors employed on the recruiting service are of opinion that the lads who enlist at present are all likely to develop into athletes, we have not another word to say. But we should have a most decided opinion of our own, if we knew that the doctors were tampered with, and were forced to make their medical opinions square with the requirements of the War Office. Mr. Childers boasted last year, that once when recruits came in too fast, the authorities, as a *first step, required that the medical examining officers should be more strict.* Can it be possible that when recruits come in too slowly, the medical officers should be required to be *less strict?* If so, the medical examination of recruits is but a farce, and England loses all guarantee, that her boy-soldiers shall be healthy boys. Lord Hartington would lead us to imagine that they are particularly healthy, but a statement may be true, and yet misleading in the extreme. He said upon inspection of the recruits enlisted, only the small number of 200 or 300 were objected to as unfit. The general reader might jump to the conclusion that the inspection referred to was *before* enlistment, whereas we believe it alludes to the inspection *after* enlistment, when the young soldier joins his corps or regiment. If so, the small proportion of objections proves nothing at all! There is no longer a regimental doctor to examine the new comers, and he would be a bold commanding officer who would take upon himself to decide that a lad was physically unfit. In fact, a specimen must be of a very bad class indeed before a regimental authority would venture to object at all. We must say we should be glad of an assurance that medical officers on the recruiting service are *never* called upon to play fast and lose with medical opinions.

Mr. Warton's Bill, to restrain the sale of patent medicines containing poison, was rejected on the second reading, on the grounds that it would not be workable, and that the Government have the matter in hand, and are prepared to treat it in "a much broader sense" than Mr. Warton had. We fear experience has proved that for the government to "have a matter in hand," means that nothing will be done with regard to it.

The General Medical Council met on Tuesday, and their proceedings on the first three days of their session are reported in another part of the journal at as great a length as the exigencies of our space, and the importance of the subjects discussed appear to warrant. The programme of business sketched in the President's speech does not promise a very exciting session, though there is no subject too unimportant for some, at least, of the councillors to think it worth while discussing. Their motto is, "Nihil humani alienum a me puto," or, as it may be freely rendered, "I am interested even in Mr. Sadgrove."

The Meeting of the Fellows and Members, at the Royal College of Surgeons, on Monday last, passed off with a certain amount of *éclat*. The Council carried all their recommendations on the one hand, while the Fellows and Members got tangible and independent concessions on the other. Both the one and the other are, to speak correctly, but recommendations to the present Council; the exact details, and the form in which they will be embodied, still remain to be decided by the Council with the help of their legal advisers, and, before becoming law, must receive the sanction of the Privy Council. We must refer our readers to another part of this journal for particulars concerning this meeting.

At the Medical Society on Monday last, Dr. Cavafy read a paper on some cases of facial erysipelas, with low temperature. The question raised was as to the real nature of such cases. Could an inflammatory process exist without elevation of temperature, especially a specific inflammatory process. Dr. Cavafy referred to the varieties of erysipelas, as indicated by the various names it had acquired, and argued from these that the disease varied greatly, both in intensity and extent, much as almost all other diseases might do, without in any way losing their specific characteristics. He rightly pointed out, that every precaution should be adopted, as regards isolation, even in cases which appeared quite simple, and apparently free from infective tendencies. Dr. Finlay next read a paper on a case of opium poisoning. The patient had accidentally swallowed a sedative draught, prepared for a horse, which contained laudanum to the equivalent of about seventeen and a half grains of solid opium. When taken to the Middlesex Hospital, the full effects of opium were manifest, and other treatment having failed, and the patient being nearly moribund, atropia in solution was injected subcutaneously; an improvement became at once manifest, and maintained itself. About one-thirtieth of a grain was used altogether. The patient quickly recovered.

At the Royal Medical and Chirurgical Society, on Tuesday last, Mr. Noble Smith read a paper on Dupuytren's Contraction of the Fingers. He had examined the hands of 700 old persons, and found 70 cases of indurated and contracted palmar fascia among them, eleven well-marked cases occurring among women; the majority of the affected individuals were mostly healthy, but very old. As regards cause, he doubted much the usual accepted theory of gout. Dr. Radcliffe Crocker communicated an account of three cases of Xeroderma Pigmentosum (Kaposi). This is a very uncommon form of skin disease, now described for the first time in this country, and is apparently a primary atrophy of the skin. From Dr. Fox's remarks it would appear that he was the first to recognise the true nature of the disease in these cases, and on account of the great rarity of the affection, he had drawings made, when they were exhibited before another society some two years ago.

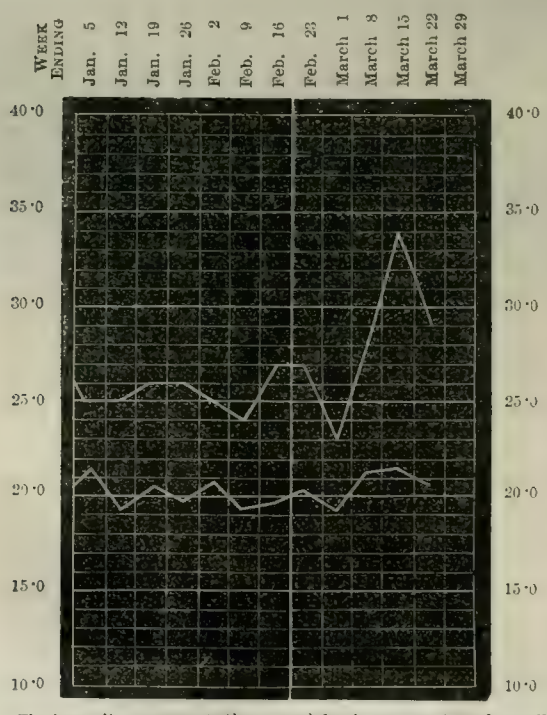
The newly formed Hospitals' Association held on Wednesday evening last the first of a series of evening meetings, of which notice has already been widely advertised. Under the presidency of Sir Andrew Clark, the rules of the Association, as approved by the Council, received the sanction of the meeting. A paper, of which a verbatim copy was placed in the hands of the members and visitors present, was then read by Mr. W. J. Nixon, the House Governor of the London Hospital, dealing with the wide and difficult subject of out-patient reform in hospitals dependent upon public charity for their maintenance. After some interesting historical observations upon the early days of the out-patient system, beginning at the London Hospital as long ago as 1741, the question of the means of reduction of the present overcrowding was considered, and the disadvantages to patients, to general practitioners, and to the honorary officers of hospitals, of any kind of pay-system was strongly urged. The injustice of limitation of numbers on the rough-and-ready principle of "first come, first served," was also pointed out, and as a true remedy a system of *inspection* of the social, and then of the medical, fitness of each patient for gratuitous relief was warmly advocated.

A paper by Mr. T. Holmes was also read, suggesting a system by which the out-patient department might be reserved for purely consulting practice, cases being sent for the purpose by their own doctors; all such work to be done gratuitously by the hospitals. The ensuing debate was both practical and interesting, the majority of speakers being able to bring personal knowledge to bear upon the subject. The system of provident dispensaries appeared to be held in considerable but not universal favour as, in theory, it will probably always remain. The association of the provident dispensary with the free general hospital is as theoretically attractive as it seems practically unworkable. A combination of the pay-system, with inspection of the social position of patients, was strongly urged by Mr. H. C. Burdett, who called attention to the success that has attended it in America, and, in the cases of the special and cottage hospitals, in England. The objections which the various methods of payment would present to the honorary officers of hospitals, were ably put by Mr. Page and Dr. Gilbart Smith, the latter being emphatically averse to any payments whatsoever. In summing up the debate Sir Andrew Clark spoke in warm terms of the value of the out-patient departments for teaching purposes, and deprecated any system by which their usefulness in that respect might be diminished.

Dr. Robert Bell, on the 19th instant, read a paper "On House Sanitation" before the Glasgow Philosophical Society. He expressed the opinion, that dishonest plumbers and builders were frequently as guilty of manslaughter as were the wretches who from time to time were convicted of that crime at the bar of justice. Dr. Bell referred to two cases, in which bad drainage had caused, in one instance, typhoid fever in four children, and in the other case a number of children had been attacked with diphtheria, as a consequence of defective drainage. It was appalling to contemplate how many valuable lives might have been

sacrificed to the avarice of tradesmen in the construction of defective drains. As a protection against bad drains the suggestion was made, that the work should not be covered in, until it had been inspected by a surveyor, and certified to be in perfect order. The recommendation was made, that the surveyor should be appointed by Government, and should be independent of plumber and proprietor. Dr. Ebenezer Duncan, in criticising the paper, said, that if sewage gas propagated fever at all (which he doubted), it did so in a very slight degree. Medical men, when they were called in to a case, and found a defect in the drainage, were too liable to put down the illness to the bad drain, especially in the case of fevers. This he considered to be a false position for any man to take up, he therefore disagreed with Dr. Bell in this respect.

The health of the 28 English towns showed a slight improvement last week, the general death-rate being 22·1 as compared with 22·6 in the previous week. The mortality from measles has been excessive at Portsmouth, Oldham, Norwich, and Nottingham, the death-rate from this disease having been as high as 7·1 in the first-named town. In London, both the general and zymotic death-rates declined last week, as may be seen at a glance from the annexed chart.



The lower line represents the annual death-rate per 1,000 from all causes in London, in each week of the current quarter.
The upper line represents the annual death-rate per 10,000 from zymotic diseases in London, in each week of the current quarter.

The former was 20·6 and the latter 2·9 per 1,000 (or, as it is represented in the chart, 29 per 10,000) and both were somewhat above the average of the last 12 weeks. The deaths from whooping-cough were less than last week, but were still 10 above the average. In the other 27 towns, with an aggregate population considerably exceeding that of London, the deaths from this disease were only 42. That is, more than 60 children died last week from whooping-cough in London, who would not have died, if the disease had only been fatal as in the other large towns. Why is this?

At a meeting recently held in King's College, a congratulatory address was presented to Professor Curnow, on his appointment to the office of Dean of the Medical Department. Planned and carried out purely by the students, the address was a graceful expression of good feeling and harmony. Numerous members of the staff were present as well as a very large proportion of the students, the wards and the dissecting room being alike deserted for the time. Dr. Wace, the new principal of King's, took the Chair, and the meeting, though brief, was throughout marked by unusual enthusiasm and good taste.

The special arrangements made for the regulation of the third Congress für Innere Medicin, which will be held in Berlin from the 20th to the 24th of April inclusive, are now complete. Exceptional interest attaches to the forthcoming meeting in the simultaneous celebration of the Jubiläum of the President, Professor von Frerichs, who will open the proceedings by an address on April 21st, and be present at a banquet to be given in his honour on April 23rd. For the accommodation of members and visitors the several committees appear to have spared no pains; and, in addition to the usual arrangements for lodgings, visits to public institutions, &c., it will be noted that places are to be specially reserved for them in two of the leading theatres. Of the subjects appointed for discussion, the most important are those of true pneumonia, polio-myelitis and neuritis, and nervous dyspepsia. Several other communications are promised, of which the following may be specially noted:—Goltz (Strassburg) on Cerebral Localisation; Herman Weber (London), on School Hygiene in England, with especial reference to Epidemic Diseases; Rosenthal (Erlangen), on Reflexes; Rossbach (Jena), on the Report of the Commission on the Treatment of Infectious Diseases. In addition to members possessing full privileges, the Congress comprises associates, who have the privilege of taking part in discussions, and of receiving a copy of the transactions, but are not permitted to vote.

The elevation of Prof. Frerichs to the rank of a noble has been received with the highest satisfaction by the Berlin Medical Press, and the profession at large. When he appeared at the Clinic the day after it had been made known, a very warm ovation awaited him. In acknowledging the compliment, he observed that he was quite aware that the distinction was appreciated not merely on personal grounds as related to himself, but also in relation to the profession of which he was a member. "We, too, most certainly," the *Berliner Klinische Wochenschrift* observes, "are of opinion that all honorary testimonials conferred upon our leaders, are reflected in the entire medical world, but Herr von Frerichs must allow us not only to express our satisfaction at the respect thus paid to the

profession, but also our joy that he has been the person selected for the expression of this honour." Conferring this rank upon professors is quite a recent occurrence in Prussia, the celebrated surgeon Bernhard von Langenbeck having been the first so honoured in recognition of his services in the Danish war. A year later, Ranke, the famous historian, was raised to this rank on his seventieth birthday. So long ago as 1866, Dr. Lauer, the personal medical attendant of the Emperor, was so honoured; and last year, at the request of the Crown Prince, the great physicist Helmholtz received the promotion. He commenced life as an anatomist and army surgeon; so that of the five persons who have been thus ennobled, four belong to the medical profession.

Dr. Koch's Sixth Report—a full translation of which we published last week—might almost have been written to exemplify the use of the Methods of Inductive Research. Curiously enough the same subject, the causation of cholera, is chosen by Stuart Mill to illustrate one of these methods. Dr. Koch found, when in Egypt, that a certain specific form of bacterium was present in all the cases of cholera examined by him. That illustrates the Method of Agreement, a method which cannot prove causation, but which is chiefly useful as affording suggestions for further research. Koch's next step was to employ the Joint Method of Agreement and Difference. He proceeded to enquire whether the special bacillus was present in the case of other diseases, especially those in which the symptoms are in some measure allied to those of cholera, as dysentery and arsenical poisoning. He found the bacillus invariably absent, and thus was able to fulfil the conditions of the Joint Method. But this method, however successfully applied, can never furnish absolute proof, for there may be some unknown antecedent—say an unexplored meteorological condition—which would account both for the growth of the bacillus and the attack of cholera, the two being thus concomitant effects of another cause, and not related to each other as cause and effect. All the while Dr. Koch was trying by the Method of Difference to obtain a definite and conclusive answer to his problem, but with such slight success that he at last gave up the attempt, comforting himself with the reflection, that it is questionable whether success will ever be attained in this direction. Lastly, his report furnishes an illustration of the employment of the Method of Concomitant Variations. He found the advance of the cholera process associated with a proportionate increase in the number of the bacilli; and this discovery, though inconclusive by itself, furnishes valuable confirmatory evidence. Since Dr. Koch concluded his labours for this year, it is reported from India that the Method of Difference has been successfully employed by a young English surgeon, Vincent Richards, who has succeeded in infecting a pig with cholera. The *Daily News*, we see, accepts this statement as conclusive, and triumphantly proclaims the completion of the discovery of the cholera germ; but scientific men will exercise greater caution, and will be inclined to hold that pig out in India innocent of true cholera, till he has been proved guilty to their satisfaction.

One most important sentence in Dr. Koch's report appears to have nonplussed our contemporary, the *British Medical Journal*. The construction of the sentence is ambiguous, but its meaning is obvious. Dr. Koch says that he often found the comma-like bacilli giving rise in pure cultivations to S-shaped forms, and to long wavy lines. The S-shaped forms, he continues, owe their peculiar shape to their being made up of two individual curved bacilli adherent to each other; and the long wavy lines consist of a series of such bacilli clinging to each other by their extremities. That is a free, but, we believe, a correct rendering of what Koch intended to imply.

A proposition has been set on foot in Vienna, to celebrate the discoveries of the German Cholera Commission by giving a triumphal reception to its three members on their return from Calcutta *en route* to Berlin. The details of the celebration will be in the hands of the Viennese Gesellschaft der Aerzte. This act of almost international courtesy will be received with peculiar favour in Berlin, coming, as it does, with especial grace from some of the keenest critics of his previous work with whom Dr. Koch has had to contend.

In his annual report to the Government of India for last year Surgeon-Major Cuningham takes the opportunity to have his say as to the alleged conveyance of cholera from India to Egypt. He considers that the fear that cholera would be conveyed from India to Egypt by ships, rests upon theoretical grounds only, and he points out that, as a matter of fact, during the long period of seventeen years Egypt was free from cholera, whereas during that time many serious outbreaks occurred in India, and he further says that it might even be shown that other countries had often commenced to suffer from cholera at a time when this was below the average in India. Had the cases first appeared at Suez or near the Southern sea-board there would, he admits, have been *primâ-facie* evidence in support of the importation theory; but the outbreak commenced on the Mediterranean side at Damietta, a town in a most unsanitary state. After pointing out the measures which are taken to prevent the supposed exportation of the disease, he says that the execution and encouragement of sanitary works is the only action which can properly be taken by the State. Measures should be adopted to improve the sanitary condition of the place, not to shut up the persons who are suffering, as that can only end in disappointment, and be productive of endless annoyance to the people.

Popular in Paris as is the Jardin des Plantes, which is attached to the Muséum d'Histoire Naturelle, the latter institution is little known or cared for, except among the men of science who are aware of the good work that has been done within its walls. Among them, however, there are several who are not pleased with its management and arrangements; and this has led the professors of the institution to issue a pamphlet (*Revue Scientifique*, March 8th), defending their procedures. One of the charges against the Muséum, which certainly seems a strange one, is that

its management is in the hands of the professors themselves, and not in those of the government. This, the professors observe, is no more than what is the case in the German Universities, and it gives to the institution an amount of independence which the professors of the French Faculties do not possess. They admit that numerous reforms and changes are required, but declare that these are not attainable as long as the sum devoted to the purpose of the Muséum is so small. The total amount of this is but 918,942 francs, out of which funds have to be provided for 19 professors, 56 assistant naturalists and preparers, a vast number of *employés*, and the keeping up of the *jardin*, which alone costs near 100,000 francs. Among the desiderata which the Director, Prof. Frémy, the writer of the pamphlet, indicates, are the providing of laboratories and a marine establishment; the allotment of a greater sum for purchasing animals (at present only 4,000 francs per annum is allotted, while a rhinoceros or elephant may cost 20,000 francs); rearrangement and refurnishing of the exhibition galleries; additional assistants; enlargement of the anthropological department and of the library (which now possesses more than 100,000 volumes); and increase in the payments made to the assistant naturalists—this last being an urgent necessity, as at present it is very difficult to fill up posts that are so badly paid.

Aconite is once more to the fore. This time it comes up for discussion on its own merits, rather than as the result of some dire calamity or crime. It is arraigned on its general character and history, and not on the issue of a single escapade in careless or criminal hands. In the debate recently held at the Société de Thérapeutique, much that was interesting, and at times entertaining, cropped up. One speaker went so far as to urge its common use in large doses, because it has been employed so much by homœopaths, that the public have developed a taste for it. "Je prends mon bien partout ou je le trouve," says Molière, and this appears to be the line of argument here adopted. The practical outcome of the discussion was useful, being no less than the recognition of the extreme variation between the strengths of preparations of aconite obtained from different geographical sources, and the importance of indicating in the prescription the precise preparation intended to be used.

It is curious to note how long it has taken our French *confrères* to realise a fact made so widely known in England at the time of the Lamson trial, Dr. Stevenson having then, and in his subsequent paper in the "Guy's Hospital Reports," shown that aconite is met with in commerce in various degrees of purity and activity. The stage of development of the plant at the time it is gathered also called for remark, M. Limousin stating that different parts of the plant contained varying proportions of the active principle before and after the opening of the flowers, and suggesting that the time of collecting should be noted in future. This is encouraging. There are *some* things we manage better in England, our "British Pharmacopœia" being sufficiently precise on this point.

The *Lyon Médical*, 16th March, reports the result of an action brought by a dressmaker against a surgeon, in which the damages were laid at 30,000 frs. The plaintiff had met with a dislocation of the elbow, and the surgeon in question, after reducing it, had applied a bandage which only reached just above and below the elbow. This was put on so tightly that the patient, suffering much pain from it, complained on four several occasions to her attendant, requesting him to loosen it. This he refused to do, declaring that her complaint was without cause; and at last she applied to another practitioner, who removed the bandage and found that the hand and a part of the arm were already in a state of gangrene. The result was that the plaintiff lost the use of her arm, and was unable to follow her occupation. Three professors of Montpellier were consulted by the Civil Court of Nimes, who, while not blaming the partial application of the bandage very severely, were of opinion that the having allowed it to remain on for 36 hours, notwithstanding the entreaties of the patient, was "an act of grave imprudence due to a false interpretation of the phenomena observed." The Court condemned the defendant in damages of 1,800 francs, and to the payment of a pension to the plaintiff of 200 francs per annum during her life.

The author of that most readable little book, "Called Back," is evidently somewhat mistrustful of the credulity of the British public in regard to his, shall we call it, "thought-seeing" scene with Pauline. He need not have been so apprehensive; those who have watched with believing eyes the wonders worked by Mr. Irving Bishop, will have no difficulty in accepting as true, so vividly described a scene. We have no doubt that the secretary of the Psychical Research Society is on the trail of the author, and we expect shortly to hear that his credibility has been vouched for by that learned body of impartial investigators. Speaking for ourselves, the antecedent improbability of of this scene is a mere trifle to one who has accepted the more remarkable feat performed by the author in one of the opening chapters, when after the removal of both lenses for cataract he practically recovers the use of his sight by dint of two years perseverance, so as almost to be able to discard the use of glasses. There could be no limits to the powers of vision of a man blessed with such a pair of eyes as the hero of "Called Back."

Dwellers in the parish of St. Marylebone, and they are many, will derive not a little comfort from a perusal of the report of their medical officer of health for last year. On the whole, the parish was fairly free from zymotic diseases, with the exception of an outbreak of typhoid fever in Harley-street, the cause of which was not clearly made out; the milk supply, of course, was incriminated, but the evidence against it was, in Mr. Blyth's opinion after a careful enquiry, inconclusive. The death rate was decidedly lower than last year, though higher in the matter of tubercular diseases, which Mr. Blyth traces to certain rookeries which still linger in the parish, but which he has got his eye upon, and will not lose sight of whilst in their present insanitary condition. Of five such regions he gives

a somewhat detailed account, showing the average number of inhabitants in each tenement, and the rate of mortality for the last seven years. In two of them this reached the rather astounding figures of 39 and 35 per thousand respectively, the average for the whole parish being twenty per thousand. We should doubt whether more than one per cent. of the thousands who daily pass the entrance to it have any idea of the existence of Gee's-court; those who have been through it will not be surprised to hear, that the mortality from chest affections is half as high again as in the rest of the parish; and there are worse places in the parish than Gee's-court.

Dr. W. J. Branch, of Basseterre, St. Kitt's, has sent us a photograph (which we regret not to be able to reproduce) of a little coloured boy in the St. Kitt's Hospital, who has two large teeth in his nose. "It was not easy," writes Dr. Branch, "to get a good picture of him, because he seemed to think that the camera was meant not to take, but to take off, his head. His lip was held up to show that all the incisor milk-teeth in the upper jaw are in their natural situations. A portion of his nose has been destroyed by ulceration. It was for this disease that he was sent to the hospital. It soon healed with the application of iodoform ointment, and the administration of iodide of potassium. I intended to have made a new nostril for him, but while waiting to make sure of the cure of the ulcer, these teeth began to make their appearance. They seem to be the two central incisors of the permanent set. They spring from the floor of the nostrils at the sides of the bony septum, are freely movable, and are apparently attached to the mucous membrane only. They have little or no roots, but their crowns are very large, white and solid. The boy's mother had syphilis many years ago, probably before his birth."

"A. B." writes to us as follows:—"You refer to the favourable opinions expressed by the American journals of the medical press of England, but singularly enough, and which I apprehend arises from an excess of editorial modesty, no mention is made of the *Medical Times and Gazette*. In an American journal now before me, I read the following, which is headed 'The London *Medical Times and Gazette*': 'Our readers who are not already subscribers to this live English medical weekly will find it a valuable addition to their libraries. The original clinical department is always interesting, some of the best men of the "mother country" being familiar contributors to the *Times and Gazette*. Our English readers in the Canadas and other provinces, as well as in the islands of Great Britain will find the editorial and news department of the *Times* of special interest to them. But we presume but few Englishmen in the profession need be reminded of this, for they probably all take the *Times and Gazette*.'"

A correspondent informs us that Dr. John Dudgeon, of Pekin, has been presented by the King of Spain with a Cabellero a La Real Orden de Isabel la Catolica, in other words, a Knightship of the Royal Order of Isabel the Catholic. Dr. Dudgeon is an Alumnus of the Glasgow University, and the Medical School, which is being established at Pekin, has been placed under his auspices. He is at present lecturer in anatomy and physiology in the Tung Wen College, and has translated several important books into Chinese.

In addition to the bequests mentioned in our last issue, the late Mr. James White, of Overtown, has left 500*l.* each to the Glasgow Blind Asylum, the Glasgow Eye Infirmary, the Glasgow Ophthalmic Institution, the Training Home for Nurses, and the Association for Relief of Incurables for Glasgow and West of Scotland. Mr. White was, as we stated recently, chairman of the Glasgow Ophthalmic Institution. All the charities of the city have lost a valuable patron by his death. The Western Infirmary will, however, be greatly helped out of a difficulty by the timely aid of its 5,000*l.* legacy, for we have intimation from the honorary treasurer that the income of the Infirmary will this year fall short by 7,000*l.* Earnest appeal is being made to the community generally, and to clerks in offices in particular, who so far are doing their best to respond to the appeal, as far they are able. It must, however, be said that there is a general tendency on the part of managers of public charities, manifestly the infirmaries, to accumulate and shut up the funds of their institutions, and then to call for increased liberality on the part of the giving public.

The lawyers have determined for us a point in which it is evident that there is considerable difference of opinion amongst medical authorities. In the case of Whitling and another *v.* Carpenter, which came before Mr. Justice Hawkins, on the 20th instant, the learned judge, after hearing the evidence of Dr. Wilson Fox, Dr. Andrew, Dr. Gee, and Dr. Lanchester, on the one side, and of Dr. Allchin, Dr. Norman Moore, and Dr. Carpenter, on the other, decided, quite correctly we think, that a consulting physician is one who acts only in consultation with another medical man having charge of the case. Dr. Carpenter, therefore, undertook to abide in future by the judge's ruling, and not to see patients except in consultation with another practitioner. We shall say nothing more of this unfortunate case, except to express the somewhat radical opinion that the time is coming for medical practitioners of all shades to give up selling the goodwill of their practices. The bargaining over patients, which such a case brings into unpleasant publicity, stamps the profession as a trade in the eyes of all men. So long as a practice is bought and sold like a public-house, it is absurd to complain of the low status of the profession. The "abolition of purchase" would at once raise the standard of the profession, by distributing rewards more in harmony with deserts.

During the forthcoming International Health Exhibition, which will be opened by His Royal Highness the Prince of Wales, on Thursday the 8th day of May, at 3 p.m., there will be a reading room and library open to the public. The Executive Council are making an appeal for the loan of works on health and

education, to be placed in the said library for reference. The books, which they are especially desirous of obtaining, are those on vital statistics, those relating to injurious trades, reports and regulations on public health issued by the Central Authorities of all countries; reports, statistics, and other works on education; and books referring to health and vital statistics in India. Current numbers of any periodicals relating to any of these topics will also be placed in the reference room. A catalogue of the books in the library will be printed, and every care will be taken to protect the books from injury. Persons willing to lend books, are desired to send them to the secretary of the library committee, Royal Albert Hall.

We are glad to hear that after a most successful first year, the *Bristol Medico-Chirurgical Journal* is to be published quarterly, instead of half-yearly, and that it is to be reduced in price.

THE PRESIDENCY OF THE COLLEGE OF PHYSICIANS.

The growing importance of the medical profession in this country, and the increased attention which is being paid to its utterances on scientific questions that affect the welfare of the people, lend an additional interest to the subject of its official representation, and of the constitution of those great bodies by which it is publicly judged. Now, more than ever, when the vital question of the status and education of medical men is again before the Legislature, and under general discussion, does it concern both the profession and the public at large that truly representative men should be called to preside over the Medical Colleges, whose advice, however expressed, should rightly have the greatest weight in guiding the actions of professional men, and influencing the opinion of Government authorities. That ancient and honourable institution, the College of Physicians, stands foremost in the capability of exercising this desirable power, and its President should be regarded as the accredited head of the profession, the mouthpiece of its best minds, and the delegated guardian of its highest interests. The present incumbent of this office has, indeed, served the profession well during the last three years, and has shown himself deserving of the best honour it can bestow. That Sir William Jenner should continue to preside over the councils of the College as long as custom permits, would meet with the approbation of all, and doubtless the Fellows would elect him again and again as long as he might be willing to keep the Chair. But when the time comes for choosing a new President, the profession, not in London only, but also over the whole length and breadth of the land, will naturally be deeply anxious that the best man in the widest sense should be elected as its representative head. Should Sir William Jenner decide not to again accept the votes of the Fellows, there would seem to be no room for doubt that the qualifications for the Presidency, which would best answer the requirements of the College and the country at large, pre-eminently meet in his contemporary, Sir William Gull. As an outspoken and unflinching supporter of scientific work and original research, no less than as a pathologist and a clinician, this physician stands second to none, and the great position he has gained in the profession, together with his wide and varied knowledge of men and things, contribute to make the interval a wide one between him and any other man of his standing. It is, perhaps, especially desirable at the present time that the holder of this important College office should be one who knows what to say and how to say it, and who unites breadth of view with firmness of speech. It seems scarcely necessary to say that the College would best maintain its own interests, while duly serving the public, by chosing for its head, when the time comes, such a thoroughly able and philosophically minded man as Sir William Gull, and not running the risk of diminishing its great influence by divided counsels, and the possible admission of some confessedly inferior representative. It is to be confidently hoped indeed that among such a body as the Fellows of the College of Physicians, no narrowness or party feeling will place any obstacle in the way of this most honourable and important office being conferred on a man whose sageness in council on public matters would be of the greatest value, and who as a great scientific and practical physician, as well as an able medical politician, has deserved so well both of the profession and the public.

EVOLUTION OR REVOLUTION?

For the third time in the history of the College of Surgeons the Fellows and Members have assembled to discuss College matters of importance, and to make recommendations to the Council thereon. But at no previous meeting have such momentous questions occupied them as those which were discussed on Monday last. We confess to a little disappointment that the meeting, comparatively speaking, was a small one; but we think this may be explained less by a want of interest on the part of members in College concerns, than by the difficulty of getting away from the responsibilities and requirements of private practice. *Per contra*, it was pleasant to see almost the entire Council present.

To say that the meeting was convened by the President and Council means much; and it would be ungracious if we were not at once to acknowledge this concession on their part, as well as the friendliness which doubtless prompted them to ask their Fellows and Members to express an opinion on the changes which they think it expedient, in the interests of the College, to make in their Charters. The majority of the changes proposed at this meeting, it is true, have reference to the working of the College, and in no way affect the Fellows or Members personally. Nevertheless one of the proposed alterations, viz., that which will give the Fellows the right of proxy-voting, is eminently a personal one, and has long been agitated for, especially by country Fellows. If it is wise to allow proxy-voting now, why has the privilege been so long withheld? The present proposal of the Council to make it legal, is robbed of a little of its graciousness by the fact that the Fellows formed themselves into an association a year or

two ago, with a view to effect this among other changes. The probable establishment, too, of a State licensing Board, which will deprive the College of the chief part of its work, and nearly all its prestige, may also be thought to have exercised some influence on the recent decisions of the once conservative and omnipotent Council at Lincoln's Inn Fields.

Of still greater import was their expressed readiness to receive suggestions or recommendations on any other alterations in the Charters which the assembled Fellows and Members might have to offer for the consideration of the Council. It only remains to see how the Council will deal with the recommendations, which the meeting was not slow to make, and some of which are radical enough in all conscience. First of all, that Members should have a voice in College matters, as well as Fellows, is obviously a step in the right direction, there being some 1,100 Fellows only, while the Members number over 16,000. Another proposal made and carried was, that an Annual Meeting be held at which the Report of the Council be submitted, received, and adopted; and that the President be no longer elected by seniority on the Council, but by a vote of the Fellows present. If the Council should accept these recommendations, and take the steps necessary to make them law, then we shall have abundant proof that at last a more enlightened policy in College affairs has been inaugurated, and we shall look forward with hopefulness and confidence to its development and results.

Up to the present time the College of Surgeons has been too purely an examining body (and not always a very courteous or considerate one). It has done absolutely nothing to foster a feeling of *esprit de corps* among its associates. From the moment that men become qualified, they cease to feel any interest in the College, which, in its turn, has fully reciprocated the feeling. Its library is very good, but inaccessible at the only times when busy men can get to it. As to the museum, we say nothing, for it does not belong to the College. Even the Fellows are left out in the cold to do as they can, save for the empty privilege of voting for members of Council, and attending an annual dinner (to which, by the way, Members are not admissible!).

How different all this from the clanship of the old universities and the public schools, which is kept up and fostered in every possible manner. We doubt very much if the members care one iota whether the new Medical Bill passes or not, now that they know authoritatively that it in no way interferes with their privileges; indeed, their indifference was manifested last year when the College, by circular, advised them to oppose the Bill in Parliament. It can hardly be doubted under these circumstances that the Bill will pass, and, if it does, that the College of Surgeons will practically cease to exist, since its chief functions will be superseded. It may continue to issue diplomas to such as care to pay for them; but as the M.R.C.S. carries no special advantages, we doubt whether the College will attract sufficient men to make this a source of income. The Fellowship may continue to hold its own for a while, but the fifteen or twenty men who acquire it each year will not add much to either their funds or their corporate power. We confess to a feeling of real regret that this should be so; and it remains to enquire whether it is past all repair. Frankly, we think not. We can hardly doubt that a most favourable impression will be produced on all the present members of the College if the newly proposed recommendations be carried out by the present Council, and if for future members a new order of things, and one adequate to the needs of the public, be initiated.

A scheme was broached at this meeting. It is one, we believe, which has often been discussed by the two London Colleges. The Colleges, it was proposed, should amalgamate, and obtain powers by Charter, to give a double diploma as doctor of medicine, and master of surgery. It was argued that in Scotland, after an examination not more searching than those of the London Colleges for their respective licences, a degree in medicine and surgery was obtained which was far more useful in practice, and carried more weight with the public than did the London diplomas, and that in consequence large numbers of men went to Scotland to study. If the London Colleges would amalgamate, and give these much coveted titles, they would be more thought of by their licentiates, and acquire more influence over them and with the public. A clause, too, might be introduced, by which those who now hold the two diplomas might be admitted *ad eundem*. With such a prospect in store, a Medical Bill would be less necessary, the Colleges being left untrammelled to work out the objects for which they were established, and in which they have gained an immense and valuable experience. The English Universities would have nothing to fear from the amalgamated Colleges, and their right to confer the title of doctor. The latter would be a licence to practise medicine and surgery only, while the University degrees would continue, as now, to be an indication of a more extended education, of wider culture, and higher intellectual powers; and they would continue to be sought after by just the same class of men as now, and carry with them just the same prestige; at present the M.D. carries less weight, than the affix Oxon., Cantab., or Lond., respectively, which qualifies it. In the supplementary Charter which would be required, the most noticeable of the safeguards which relate to the efficiency of the profession and the welfare of the public, contained in the new Medical Act, could be inserted, and made operative in the new scheme. For the present, we must leave the subject, but shall await with interest the deliberations of the Council on all that has transpired. Let us add, "Baldgethan ist wohlgethan."

The Hospital for Sick Children, Gt. Ormond St.—The annual festival of this charity was held on Wednesday evening, March 26th, at Willis's Rooms, when Sir William Gull, Bart., presided. The Chairman, in the course of an eloquent speech which was characterised subsequently as philosophic by Lord Gort, spoke of the value of such an institution, and of the deservedly high reputation which the hospital enjoyed in the medical world. What he had seen of the hospital and its nursing arrangement pleased him very much. In the course of the evening the Secretary announced that the subscriptions and donations amounted to 1,700*l*.

THE NERVOUS ELEMENT IN ABDOMINAL DISORDER.

THE material of the Gulstonian lectures this year offers several points for reflection, both in its negative criticism and its positive teaching. The first lecture, which so admirably and trenchantly marks the ethical iniquities so often following in the train of pseudo-science, cannot fail to be of the greatest practical value to the profession and the public. Good service, moreover, will doubtless be done by the lecturer's insistance on the purely symptomatic character of the word dyspepsia, though we cannot but think that the majority of teachers in London almost daily emphasise this dictum before their pupils as strongly, if not as eloquently, as Dr. Allbutt himself, and that the fallacy he combats is not so common among practitioners in the South as it seems to be in the North. But our present remarks will relate chiefly to the positive scientific precipitate apparently left from these Lectures on Visceral Neuroses after the filtering off, for due preservation, of the potent solution of well-merited moral and practical reproof which the lecturer has placed before the profession.

Many have undoubtedly been impressed by Dr. Allbutt's contention that cases of gastric and intestinal pain and disorder, apart, in all probability, from visible organic disease, are of such frequent occurrence; cases, too—as was so much insisted upon—that do not show any obvious alliance with the symptoms popularly known as hysterical. Although something must be put down to the exceptionally large experience of Dr. Allbutt in abdominal cases, and possibly also in some degree to the *locale* of his practice, yet it must be admitted that what we must call true neuralgias often occur which have their seat below the diaphragm, and that other symptoms, such as sickness and flatulence, are not seldom seen whose course and alliances seem to point to a nervous origin similar to that of the pain with which they may or may not be associated. But when we conveniently refer these cases of pain and discomfort to the heading of "visceral neurosis," it is well that we should pause and ask ourselves what we mean by the term "neurosis." This word seems to be used in two different senses. First, it is employed with the implication that the organ affected is not permanently or structurally diseased, but that it is simply disturbed with a disturbance of the nervous system. This we may call the negative connotation of the word "neurosis," and perhaps more than any other it makes the use of the term both justifiable and necessary. By styling a symptom neurotic, then, we mean that the suffering part of the body is not locally diseased, and does not require local treatment; and that, whatever the general cause of the disturbance may be, a large field of doubt as to its nature and treatment is removed.

The second use of the word "neurosis" is more vague, but we think fairly common. It shines through the application of the term neurotic to a certain class of people, and apparently implies a theory of some special diathesis, so that when we call a patient neurotic in this sense we refer him to a peculiar though vague pathological category. If we mean anything by marking a sufferer as neurotic, we imply that there is some undiscovered fault in the development, or organisation, of his nervous system, or, to use Dr. Allbutt's words, that there is an atony or a special irritability of nerve element. Now, although this is a laudable attempt at explanation, or at reduction of disorder to order, it is evident that it is but an attempt. In the present state of our knowledge of nervous physiology or the study of normal nerve function, we are but on the threshold of an enquiry which we may never satisfactorily terminate. We are here, at the best, in the presence of a great Unknown, and, however probable it may seem that many maladies at present referred to other systems may be really neuropathies, and that we may be able some day to trace "even the history of gout upwards to a point of union with a divergent stock that has previously branched off into the tuberculo-neurotic," yet we run at least the risk in prematurely doing this of employing the method of *obscurum per obscurius*, and possibly of neglecting some more subordinate cause which may lie immediately at our feet. A faulty development of the nervous system, that highest and most complex expression of organisation, is obviously likely to be the lot of many of us, and though this may be the only possible interpretation of many so-called nervous symptoms, we must still confess that the explanation as yet savours of learned ignorance, and often comes very near to a laboured acknowledgment that we are unable to explain the symptoms at all.

This being the case, it behoves us to be very careful as to the sense in which we apply the term "neurotic" to disease, and we are here brought to consider how far the distinction insisted on by Dr. Allbutt between "neurotics" and "hysterics" is scientifically valuable. That a laborious student, who is the subject of gastric neuralgia, is not to be clinically classed with the wilful or will-less girl, who month after month lies helpless, though apparently healthy, in her bed, is quite clear to all, and is beyond discussion. It is unquestionable that there are many sufferers from real pain and discomfort, the explanation of which is not obvious, whom it would be absurd to accuse of simple fancy, and still more to arraign as conscious impostors: and here we quite agree with Dr. Allbutt in condemning the application of the popular term hysterical, implying a large element of shamming, to every pain which cannot be referred to a tangible cause. But if we analyse the symptoms which in medical language generally are called hysterical, including many which often occur in those to whom Dr. Allbutt himself would apply the term, we shall probably find that they can be best, if not exclusively, explained by ranging them under the term "neurosis," according to the meaning laid down above. A disordered nervous system, *i. e.*, a want of proper subordination in the working of the various parts; an abolition of due control of the higher over the lower "centres" (which, indeed, is only the physical expression of want of will), an undue reaction to stimuli—formulæ such as these and others state really all that we can mean by the term "neurosis," and these conditions find their best and most varied illustrations in those patients who are

admittedly called hysterical. Surely, if we are to keep to the old eruse of the term, as Dr. Allbutt seems inclined to do, we must regard *clavus* as an important expression of hysterical disorder; for it frequently occurs in patients who exhibit the other marks of hysteria in its most limited sense. Taking, indeed, the symptoms of hysteria together, including the mental and moral failures so prominently brought forward in these lectures, and demurring here only to Dr. Allbutt's allowing his moral indignation to get the better of his physical philosophy, we should rather plead that hysteria, including, as it does, the disorder of the highest cortical centres which express the intellect and the will, is, *par excellence*, the purest example of neurosis in its most legitimate sense. For is it not a Protean manifestation of disorder from the apex to the base of the nervous system, motor, sensory, and nutritive, eluding our most careful search for subordinate and more tangible causes.

The paralysis of the so-called "will" deserves the attention of the physician as much as that of a limb, or the undue expression of pain in any part of the body, and must be looked upon in close connection with the more strictly bodily disorders which often accompany it. It must be remembered, too, that the disturbances of hysteria, both in its normal and intellectual phases, are often conjoined with the so-called neurotic phenomena of gastric pain, and more especially of flatulence, on which Dr. Allbutt lays such great stress in his exposition of pure neuroses. Dr. Allbutt admits, indeed, that the hysteric is a degenerate member of the neurotic family; but our contention is that this simile is not accurate, and does not quite save the lecturer from the charge of making a somewhat artificial and premature division of functional nervous disorders, and an apparent attempt at pathological finality but hardly justified by our scanty physiological knowledge. Some degree of confusion, and, indeed, practical mistakes, might possibly be occasioned with not very profound observers by accepting too unreservedly the lecturer's view. Rather should we call the hysteric patient a *multum in parvo* of neurotic disorder, a museum of nervous aberrations, while Dr. Allbutt's neurotic, or, what is not far different, the neuralgic, is but an isolated specimen of disordered nerve function. It is when the higher parts of the nervous system become deranged that the confessedly hysterical symptoms set in on which in ethical rather than medical language Dr. Allbutt has poured out the vials of his contempt. It would almost seem that sensory nervous disorder accompanied by pain is reserved by the lecturer for the honourable title of neurosis, while the motor and other disorders of function, unattended by actual suffering, and therefore more liable to the suspicion of shamming, are relegated to the class of hysteria in its narrowest and most offensive sense. The "neuroses," for instance, of vomiting and flatulence, often, as Dr. Allbutt says, unconnected with prominent pain, must be admitted to be very common, indeed most common, in obviously hysterical women; so that it is scarcely straining the meaning of the lecturer too much when we substitute the word "neuralgic" for the "pure neurotic"; for it is, indeed, the neuralgic who pre-eminently justifies at first sight the plausible creation of such a clinical class at all.

A practical lesson to be learned from this seems to be, that the more a pain or other nervous symptom is localised and constant, and unassociated with other signs of nerve-disturbance, so much the further is it removed from the hysterical class, or from the typical neurosis; and just in the same proportion is it often found to be very difficult to distinguish from affections with a more tangible origin. Apart from any hypothesis of a nerve origin for the round ulcer of the stomach, is it not often a very puzzling task to make a certain diagnosis between gastric ulceration and gastralgia? They are apt to occur in the same class of subjects, and the symptoms of the two affections, if accurately described in certain cases, would sometimes be almost indistinguishable on paper, or indeed in actual practice We find Dr. Allbutt himself more than hinting, from time to time, at some other explanation for the localised troubles he so accurately describes than that of pure neurosis; and suggestions are made as to an "echo of gout" in some cases, and a remnant of rheumatism in others. We are by no means implying, it must be well understood, that there are no such patients as Dr. Allbutt's privileged class of neurotics; but rather desire to point out that the line must not be drawn too distinctly round them. We must never forget the obvious conditions which, as ample experience tells us, often underlie neuralgia in its many expressions; and bearing in mind the part played by bad nutrition, bad air, worry, and, their frequent resultant, anæmia, no less than gout, rheumatism, and many other causes, we shall probably have a clearer idea of what we are about, than by a too dogmatic and frequent use of the word "neurosis." While fully admitting the important element of functional disturbance in the complaints of humanity, we must always enquire first into the question of tangible causes of disease; and, on the other hand, when we come to deal with the obviously hysterical patient, let us remember that she or he is none the less a morbid specimen. It is mainly because it seems possible that both these precautions may be treated somewhat lightly by many who may read Dr. Allbutt's lectures without sufficient care or reflection, that we have ventured to point out these over-nice distinctions, and the somewhat arbitrary use of terms, which are the only faults we can find in these otherwise suggestive and memorable lectures.

WELDON *v.* WINSLOW

The termination of the case of Weldon *v.* Winslow is to both parties partly satisfactory and partly unsatisfactory. To the plaintiff it is satisfactory, insomuch that no one can doubt that she is, at the present time, a sane and very intelligent, not to say astute, person; while it is disappointing to her to know that she has, in the words of the judge, "no redress for the serious inconveniences to which she has been put." The defendant, on the other hand, has been completely acquitted of malicious intention, and is shown to have acted throughout in strict accordance with the law, and to have been guided by what he considered to be the best interests, both of Mr. Weldon who consulted

him, and of Mrs. Weldon herself. On the other hand, he has been subjected to a cross-examination which was calculated to place him in a ridiculous light before the world; and the history of the occurrence, as well as the subsequent events, has shown that the course he took was in itself injudicious, and that the affair was, as he himself admitted, wofully mismanaged. Dr. Winslow was asked by Mr. Weldon to see Mrs. Weldon, and give an opinion as to her sanity. He reported to the husband that she was insane, and recommended her removal to an asylum. It was then arranged that he should himself receive her into his own private asylum at Hammersmith. This will appear to an unconcerned spectator as a false step. The law has provided, and very righteously and properly provided, that the formal certificates, upon which a patient is admitted to a private asylum, shall not be valid if signed by the proprietor of the asylum, or by any one pecuniarily interested in it. The law does not take cognisance of informal proceedings, and, therefore, Dr. Winslow's proceeding was strictly in accordance with the letter of the law; but it was wholly contrary to its spirit. In this case the visit and report of Dr. Winslow were the real and moving cause of Mr. Weldon's decision to send his wife to an asylum. The certificates of the other medical men were obtained merely *pro formâ*—to satisfy the requirements of the statute. Doubtless, the necessity of obtaining them constituted a safeguard to the patient; but the fact remains, that the principal person concerned in getting Mrs. Weldon committed to Dr. Winslow's asylum, was Dr. Winslow himself. It was he who recommended her removal, and it was he who chose the medical men who certified to her insanity; and this, we repeat, was in direct conflict with the spirit of the Act. One of the circumstances of the formal examination did not attract attention at the trial, which is the more remarkable, since a precisely similar procedure, in another case, was commented on by the presiding judge, some time ago, in terms of great severity. The Act provides that the examination, whose results are set forth in the certificate, shall be conducted by the certifying medical man "separately from any other practitioner." In the case of Mrs. Weldon, and in the previous case to which we refer, the two certifiers went to the house of the patient together, and first, one of them waited outside the room while the other examined the patient; and then the two changed places. In this proceeding again the letter of the Act was complied with, but its spirit was certainly violated. Surely, if the provision of the Act is inserted for any purpose beyond mere caprice, it is in order that the two investigations shall be wholly independent of one another, and that the view of one practitioner may not be biassed by the view of his associate. But how can two examinations be considered independent if the two practitioners go to visit the patient together, and first one goes outside the door for ten minutes, and then the other? In a very exceptional case, if a patient is raving so as to disturb the neighbourhood, or so violent and destructive as to endanger the lives of those around, such a proceeding might conceivably be justifiable; but no such necessity was shown to have existed in the case of Mrs. Weldon; and in the absence of urgent necessity, such a narrow and bare conformity with the letter of the Act is almost disingenuous. It has an unpleasant appearance of sharp practice, which a wise man will do well to avoid. It is probable that this part of the proceedings was present to the mind of the judge, when he said that the proceedings had been "strangely precipitate," an expression which was, under the circumstances, not too emphatic.

REVIEWS AND NOTICES OF BOOKS.

The Operative Treatment of Intra-thoracic Effusion; by Norman Porritt, L.R.C.P. (Fothergillian Prize Essay, 1883.) Messrs. J. and A. Churchill, pp. 307.—The favourable verdict already awarded to this treatise by the adjudicators of the Fothergillian Medal is in itself a substantial recognition of the excellent manner in which the work has been carried out by its author. The compact volume at present before us contains the original essay, with hardly any alterations or additions of importance. Confining himself strictly within the limits of his title, the author devotes the greater part of his work to the discussion of the operative treatment of the various forms of pleural effusion as being by far the most frequent, if not the most important, of all the intra-thoracic affections with effusion. A short but carefully written account of the principal points in the anatomy of the thorax is followed by a general statement of the methods of operating upon the chest, the term paracentesis being exclusively applied to the close operation, as with the aspirator or guarded trocar, the term thoracentesis being in like manner reserved for the open operation by incision. A more detailed account of the methods of carrying out these operations, the difficulties attending them, and the sequelæ favourable or unfavourable that are liable to follow them, is reserved for individual chapters. Many of the arguments adduced for and against the various procedures described are of necessity derived from other writers upon the same subject, but the author has not failed to make intelligent use of such personal experience as he has had the opportunity of enjoying. In the simple operation of paracentesis he advocates the use of syphon action by means of a long indiarubber tube firmly attached to the canula, the trocar being thrust through the wall of the tube before entering the canula, so that on withdrawal, the elastic recoil of the tube at the site of puncture prevents all entrance of air into it. He claims for this method a decided advantage over the use of the aspirator, on the ground of its greater simplicity and more graduated and controllable action, and in this view he would probably be supported by most physicians of large experience in such cases. In many of the larger hospitals in London this mode of tapping through an indiarubber tube arranged as a syphon has been long since established as a routine procedure.

In dealing with empyema the author attacks his subject in a systematic fashion, discussing the question of operative treatment fully in all its bearings. If only from a historical point of view the section will amply repay perusal, containing as it does an interesting comparison of the views of the older and more modern writers, both as to the various forms of operation, and as to the respective advantages and disadvantages which they present. The practice of excising portions of ribs is condemned as a primary method of drainage, and after full discussion, Mr. Porritt, while "deprecating delay," would postpone resection in the uncured cases until six months had elapsed. The operation is usually undertaken for one of two reasons: either to facilitate the escape of retained pus, or to permit of greater contraction of the chest-wall. In either of these cases the indications for the resection must be manifest in a far shorter time than he would allow, and hence to delay the operation after its necessity has become obvious is simply to delay, if not to jeopardize, the patient's chances of recovery. Of the operative treatment of pneumothorax and of pericardial

effusions a short account only is given. The book is concluded by an appendix of clinical cases occurring under the author's observation. Although not adding appreciably to the common fund of knowledge on its subject, the work deserves recognition as a careful and painstaking collation of the teachings and opinions of most of the best workers in the same field, brought together and employed with discrimination by a conscientious observer. The style of writing is distinct and simple, being only disfigured by a frequent interchange of the personal "I" with the editorial "we." The printing and compactness of the book leave nothing to be desired.

The Refraction of the Eye: a Manual for Students; by Gustavus Hartridge, F.R.C.S. London: J. & A. Churchill, 1884.—Mr. Hartridge gives in a sufficiently clear and concise manner all the facts requisite for diagnosing and correcting errors of refraction. He commences, in a preliminary chapter, by a short statement of those optical laws which bear on his subject. After treating of the refractive system, accommodation, and convergence from a physiological point, the author describes the various methods of determining errors of refraction. He is not, however, very accurate in his account of the objective examination of the patient. As an example we give the following:—"A flat-looking face is frequently an indication of hypermetropia, a head elongated in its antero-posterior diameter, with a long face and prominent nose, indicates myopia." We notice with pleasure the prominence given to the subject of retinoscopy or umbrascopy—a more correct term, as Mr. Hartridge considers, though he does not recommend its use. "The method of employing retinoscopy is so simple that a few practical trials will suffice to make it understood, although of course, as in all other manipulations, some little practice is required. . . . I think it without doubt the most valuable and trustworthy of all the objective methods." With this opinion we thoroughly agree. In the remaining chapters, the abnormal conditions of refraction, strabismus, and asthenopia are fully and, on the whole, accurately discussed. We think, however, that the following statement would not meet with general acceptance. "Myopia almost invariably depends upon a lengthening of the visual axis, due to the formation of a *posterior staphyloma*." Though the book contains some errors other than those we have quoted, we yet consider that it gives a very convenient and thoroughly practical account of the rather difficult subject of the refraction of the eye. It is well printed, and the illustrations are good.

Principes de Thérapeutique Générale; par J. B. Fonssagrives. 2me. édition, revue avec soin. Paris: J. B. Baillière et Fils, 1884.—Though M. Fonssagrives, as a cultivated Frenchman, is not open to the reproach of dulness, an essay of 575 pages on drug-action in general, culminating in a classification of remedies under 206 separate heads, with sub-divisions, is unlikely to meet with much attention in this country at the present day. The author's opening sentence, "On généralisait trop jadis; nous ne le faisons pas assez aujourd'hui," is the key-note of most of his chapters, which are "generalised" to the point of platitude. M. Fonssagrives entertains the familiar objections to accepting the results of experiments on the lower animals, which accordingly he quotes only as far as they fall in with his own views. Thus unfettered, he skips airily enough over the ground which duller men are laboriously tilling, and arrives at his conclusions with unbated breath. When we mention that digitalis is classed, with the vegetable and mineral acids, as a "sedative of the circulation," that the action of strychnia is explained without reference to the spinal cord, and that ammonia is unhesitatingly paraded as the one true antidote to animal poisons, it will be sufficiently clear how little M. Fonssagrives' system has to do with what is generally regarded as modern therapeutics.

A Manual of Nursing: Medical and Surgical; by Dr. Cullingworth. J. and A. Churchill.—If the nursing, both in hospitals and in private practice, is not even yet all that physicians, surgeons, and the public could wish it to be, it is from no lack of useful manuals. The present one appears in reality to be a second edition of a former work, but one which has undergone such alterations, amplifications, and improvements, that we must needs regard it as a new book. It is illustrated; the directions are short and concise, and if applied with a due modicum of *νους*, the result will be entirely satisfactory. The author justly observes, however, that it will only be found useful as an auxiliary to personal teaching at the bedside—"a mode of instruction which no text-book can ever supersede."

ABSTRACTS AND EXTRACTS.

MEDICINE.

The Exchange of Gases in Fever.—Lilienfeld has recently conducted some experiments on the exchange of gases in animals in a state of fever. (*Pflüger's Archives*, Bd. XXXII., pp. 293–356.) The experiments were made in such a way that he was able to determine during a long period the interchange of oxygen and carbon dioxide—(1) when the animal's temperature was normal, (2) when it was thrown into a state of fever by the injection of a putrid infusion of hay. He found that, without exception, both the absorption of oxygen and excretion of carbon dioxide were increased in fever, and also that the influence of the fever was greater in an animal which had been starved than in one which was fed up to the time of beginning the experiment. This difference he refers to the fact that in the last case the sudden cessation from feeding would alone diminish the amount of oxygen required. He also found that the ratio of the carbon dioxide expired to the oxygen inspired was not altered by the fever. This constancy of the respiratory ratio $CO_2 : O$ proves that Senator's assumption, that in fever the processes of oxidation are incomplete, cannot be accurate; but that the amount of tissue change is increased in fever, whilst the processes of oxidation are carried on in the same manner as in health, but to a greater degree. This increase of the processes of oxidation cannot be a consequence, but must be the cause, of the rise of temperature, since it took place in animals injected with the hay infusion, although their temperature was prevented from rising by keeping them in a bath at a suitable temperature. In one experiment even, in which the temperature of the animal's body was kept below normal by means of the bath, the interchange of gases was increased, this being probably due to the artificial cooling causing a compensatory increase in the production of heat. The author here again agrees with Finkler that the body has the power of regulating its production of heat in a state of pyrexia, as well as in health. Lilienfeld agrees with Zuntz that the rise of temperature, so far from being a salutary reaction of the animal's body in order to destroy the cause of the fever, is rather prejudicial to it, and at the same time favourable to the development of the pyrogenic organisms. —*Centralblatt für Klinische Medicin*, January 19th, 1884.

Arteritis as a Sequela of Enteric Fever.—An interesting communication on the above subject has been made to the *Revue de Médicine* (*vide* Nos. 1 and 2 for this year) by M. Barié. The conclusions at which he arrives may be summed up as follows:—Acute arteritis after typhoid fever is especially liable to occur in the main arteries of the legs, and is generally uni-lateral. It comes on at the commencement of convalescence, just as the patient is beginning to walk again, and is as likely to follow a mild attack as a severe one. He makes out two forms, viz., acute obliterative arteritis, and acute parietal arteritis, but they differ only in degree. The former is the result of a cellular infiltration of all the coats of the artery with a roughened state of the lining membrane; this is followed by the formation of a thrombus firmly adherent to the walls. If the obstruction is complete and there are no anastomoses, dry gangrene speedily makes its appearance. The chief

symptoms and signs are pain along the course of the arteries, sometimes limited, at others extending the whole length of the limb, and increased by pressure or exertion; marked diminution in the fulness of the pulse wave; swelling of the affected limb without œdema or redness, but followed sometimes by a violet mottling; lowering of the temperature of the affected limb; and lastly the appearance of a hard and painful cord along the course of the artery. The parietal form is to be distinguished from the above by the general mildness of the symptoms, the absence of the cord-like swelling or dry gangrene, and by the fact that recovery always takes place. As to whether the symptoms might not be due to embolism, could only be decided by a careful examination of the heart, and a search for other signs of embolism. M. Barié is of opinion that typhoid arteritis results from two principal factors, viz., local and permanent irritation by parasitic and infectious germs, and profound disturbance of the vaso-motor nerve supply.

Dependence of Asthma on Disease of the Nose.—Macini describes, *Gazz. de Osp.*, 1883, No. 77-79, three cases in which he believes that asthma depended on a pathological condition of the nasal mucous membrane. His first case was a woman, aged 40, who, with the exception of slight emphysema and bronchitis, was in good health. For the last two years her nose had been partly stopped up, and she was obliged to breathe constantly through her mouth; she frequently suffered from true asthmatic attacks, chiefly by night. On examination it was found that the nasal mucous membrane was greatly swollen, and that completely blocking the nostrils with cottonwool increased the severity of these attacks. The nostrils were made pervious by the galvano-cautery, with the result of curing the attacks, and enabling her to sleep peacefully. The second case was that of a woman, aged 34, whose right nostril was blocked by mucous polypi; her difficulty of breathing was cured by removing the polypi. The third case occurred in a man, aged 40, who had suffered from his youth from frequent attacks of coryza and difficulty of breathing. He gradually grew bronchitic and emphysematous, and his nose became blocked by considerable swelling of the mucous membrane. His difficulty in breathing increased gradually, till he suffered from attacks of true asthma. As soon as the obstruction in the nose was removed his asthmatic attacks became very much less severe. Macini considers that in these cases the asthmatic attacks were reflex, caused in susceptible persons by a peripheral stimulation of the nerves in the mucous membrane of the nose.—*Centralblatt für Klinische Medicin.*

Rheumatic Hyperpyrexia.—In the *Birmingham Medical Review* for March, Dr. A. H. Carter records a case of this kind, in which a good result followed the employment of the graduated cold bath. In discussing the cause of the excessive fever, he points out that it is the changes which take place in the tissues themselves during the process of oxidation which must be regarded as the proximate cause of fever. These changes own some restraining influence, probably they are under the control of the nervous system. Assuming this to be correct, it is easy to understand that central nervous disturbance, characterised by a certain degree of depression, would be attended with the loss and abolition of the controlling influence referred to, and would be followed by unrestrained destructive changes in the tissues, and the production of an excessive amount of heat. This theory receives support from the presence of nervous symptoms in these cases, for delirium and, to a less degree, insomnia and restlessness are always present. As in these cases the delirium often precedes the rise of temperature, it is clear that it cannot be attributed to this cause, and both probably depend upon some functional central nervous disturbance. The occurrence of delirium in rheumatic fever, if not due to some complication, such as pericarditis, should always make us on the look-out for hyperpyrexia.

Diabetic Neuralgia.—The symptoms of this form of neuralgia, which M. Cornillon (*Revue de Médecine*, March, 1884) would have us to accept as a distinct malady, are much as follows. The onset is sudden, the patient being seized either during the night or on waking with the pain, which may be continuous, may be boring, lancinating, or lightning-like, and is liable to paroxysmal exacerbations. It does not usually come on till the disease is well established. The early morning, the evening, and just after meals are the favourite times for an attack. The pain may be in the muscles and bones, as well as in the nerves. Pressure along the course of the nerves usually exaggerates the suffering. A very marked feature of the affection is its symmetry, which tends to be very exact, though it generally appears on one side first. Of course every neuralgia occurring in a diabetic is not necessarily to be regarded as having a causal relationship with the glycosuria; the points on which we should lay stress in diagnosis being the spontaneous character of the pain, its extreme severity, its abiding nature, and its symmetry. As to the pathogeny of the affection, M. Cornillon considers that the available evidence points to some close association between it and the uric acid diathesis, a connection supported by the fact that, as in gouty neuralgia, the sciatic nerve is the favourite seat of the disease. He believes that the central nervous system (spinal cord) is at fault, but what the exact lesion is he does not surmise. Strict attention to diet and alkalies generally suffice to effect a cure.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, March 25, 1884.

Dr. George Johnson, F.R.S., President, in the Chair.

Seventy Cases of Dupuytren's Contraction of the Fingers.

Mr. Noble Smith communicated a paper on this subject, of which the following is an abstract:—

Upon examination of the hands of 700 elderly people, 70 cases of indurated and contracted palmar fascia were found. The points to which attention was chiefly directed were (1) the supposed immunity of females from the affection; (2) the cause of the malady; (3) its treatment. 1. Among 440 women were found fifteen cases of indurated, thickened, and contracted fascia alone, and also eleven cases of well-marked Dupuytren's contraction of the fingers. Drawings of some of these cases were shown. 2. As the disease had been attributed to gout or rheumatism, enquiries were directed as to these diseases, and the evidence was against their being the cause. The majority of the individuals were free from common complaints, and seemed tolerably robust; they were mostly old people, the average age being 73; twelve were over 80. Most of them attributed the contraction to some particular kind of work. The much greater frequency with which the right hand was found affected, led one to the supposition that *use* has a material influence. In some cases the hands had, however, been very little used. Some cases occurred from injuries in which the contraction and thickening were exactly similar in appearance to the others. In many cases the hands were affected symmetrically, indicating some other than a local cause. Contraction of the palmaris longus was almost constantly present, and it was thought possible that this might indicate a condition of nerve irritation in some instances. 3. With regard to treatment, the author recommended operation upon the contracted bands of fascia by as few incisions as possible, as opposed to the recommendation that many incisions should be made. The object being to separate the cut parts as much as possible, so that recontraction would be prevented. Cases were recorded to prove the value of this recom-

mendation. It was probable that section of the palmaris longus tendon might be beneficial in the early states of contraction.

Mr. ADAMS thought Mr. Smith's paper a valuable contribution to our knowledge of this affection, which latterly had been attracting considerable attention, especially in America. Dr. Keen, of Phildelphia, had recently published an exhaustive memoir on the disease, and had collected together the largest number of cases that had ever been published. He (Mr. Adams) enquired why the cases occurring among the males had not been sub-divided into two classes, as had been done with the females. The percentage of cases of disease to the number of persons examined was large, viz., ten per cent.—he could not believe that this was anything like correct for the entire population. But if the hands only of a particular class of population were examined, some explanation appeared to be thus afforded. The number of women affected was much larger than his own experience would have sanctioned, and Keen's statistics also contained a smaller percentage of women than Mr. Smith now recorded. Keen believed in a purely local origin. He himself believed the cause to be gout, a disease not infrequently localised itself. His reason for thinking it due to gout were the hereditary nature of the affection; its symmetrical character, and that it attacked both sexes. It was further a disease neither of the labouring classes, nor of artisans, but rather of professional men of the middle and upper classes. As regarded treatment, he believed in a large number of incisions rather than a few as now advocated by Mr. Smith.

Professor HUMPHRY said the meeting had heard two views as to the causation of this deformity, viz., a gouty cause, and a local one. As in many other cases, he thought the truth lay between the two, rather than in either alone. This contraction occurred chiefly in connection with the ring-finger; it was doubtless due to the greater pressure exercised on the corresponding part of the palm by the walking-stick or umbrella, as the case might be, and was symmetrical owing to similarity of the predisposing cause. The metacarpo-phalangeal joint became first affected, then the disease spread to the phalangeal joints. He could scarcely think it depended on contraction of the palmaris longus, but if so, why should it chiefly affect one finger, and not all four fingers. It was curious that a similar deformity did not exist more often in the foot—perhaps it was due to the fact that the foot was always extended; while the metacarpo-phalangeal joints were the more frequently flexed. When it did occur in the foot, it was noteworthy that it affected the phalangeal joint, and was due to contraction of the tendons, while in the hand it was due entirely to fascial contraction, and occurred first at the metacarpo-phalangeal joint.

Mr. CROFT, while admitting that a gouty history was most frequently present in these cases, yet felt, if a few cases occurred in which no such history could be obtained, that there must be some other cause, and that the circumstance was of considerable interest. As regarded the palmaris longus, he thought, as its first action was to flex the wrist, that the wrist ought to be more frequently affected, if its contraction was the real cause of this deformity. Then we should have to be quite sure that it was present in all the cases: in the dissecting room it was found to be frequently absent. He was disposed to hold with the method of treatment by multiple incisions, rather than by a few.

Mr. WALSHAM agreed with Mr. Adams, that multiple incisions was the better treatment; he had tried both, and had come to this conclusion. He advised, however, that the incisions should be made opposite the folds of skin, and not in the furrows. He had not been able to satisfy himself that the disease had any connection with gout.

The PRESIDENT was not satisfied with the evidence that the deformity was gouty; he doubted, for instance, whether, in the patients shown, their habits of life had been such as to lead to gout, and whether they had inherited gout from their ancestors. Then, as Professor Humphry had said, why was it so seldom found in the feet, where gout was ordinarily so common. It might, nevertheless, be due to constitutional cause, other than gout.

Mr. NOBLE SMITH, in replying, said that the only way in which he could account for there being so may as ten per cent. affected with this contraction, was that all the people examined were very old, and in many the contraction had only commenced a few years ago. He had been very careful to exclude all doubtful cases. As to the cause, he thought that the facts he had collected bore strong evidence against the theory of a rheumatic or gouty origin, at least as far as the class from which his cases were obtained was concerned, and he was glad to be supported in this view by the President and by Mr. Croft. He thanked Professor Humphry for his very valuable observations. His paper was a statement of facts rather than theories. With regard to treatment, he still urged the desirability of making as few incisions as possible, with the view of separating the cut ends of the fascia, and preventing reunion and consequent recontraction. He agreed with Mr. Walsham that a sufficient number of cuts should be made to relieve the contraction, but he thought they should be as few as possible. He had seen, and he knew that other surgeons had seen, recontraction follow operation by multiple incisions, whereas in the several cases recorded of rupture of the restricting band of fascia by accident in which case there would be only one division, the contraction had been permanently relieved. In one of the cases mentioned in his paper, the good results remained at the end of twenty years, while the fingers of the opposite hand had in the mean time become contracted. The case represented in two of the drawings, he had operated on in this manner most successfully. Then if such good results could be obtained by a few divisions, surely it was more desirable than making a large number. The latter operation required a much longer time for its performance, and necessitated the use of an anæsthetic, besides which, he thought, he had shown that the ultimate result of the operation, as he performed it, was more likely to be successful than when a great many divisions were made. He was glad that his paper had produced so much interesting discussion.

Three Cases of Xeroderma Pigmentosum (Kaposi).

Dr. RADCLIFFE CROCKER communicated a paper on this subject. The disease, of which the three cases brought forward were examples, was first described by Kaposi in Hebra's "Diseases of the Skin," in 1870, and last year he gave a more extended account of it. These were the first and only cases of the kind known in England, and consisted of two sisters, aged respectively twelve and ten years, and their brother, aged nine, out of a family of four. Besides the above cases there were thirty-one others known, all bearing to one another a striking resemblance. The disease usually commenced in the first or second year without apparent cause, affecting the exposed parts of the face, neck, and extremities. It spread slowly, reaching as low as the third rib in front and up to the middle front of the upper arm. In the first stage red blotches or spots appeared, which faded, leaving lentiginous pigment spots; or the freckles might be the first noticed, and tend to increase in number, size, and depth of colour. Soon the skin became very dry, and white atrophic spots appeared between the lentigenes, which coalesced into larger areas. The skin in parts peeled off in thin lamellæ, and subsequently became contracted and parchment-like. Some years after the onset superficial ulcerations covered by crusts appeared, and verrucose projections could be felt in the position of some of the pigment spots. These terminated the second stage. From the fourth to the sixth year the third period began. The verrucose projections and the sores became the starting-point of fungating epitheliomas. The patients, whose general health had previously been entirely unaffected, became marasmic and died exhausted, or, in a few cases, from generalisation of the cancroid tumours. Death usually occurred before puberty, but both onset and termination might be deferred. Of the whole thirty-four cases the number of males and females

affected was equal, but if attacking several members of a family, it usually limited itself to the members of one sex only: seven boys having been affected in one family, and five girls in another. Other ætiological factors were few. Congenital but not hereditary exposure to the sun had been suggested as a possible exciting cause in a few cases, but distinct evidence was wanting on this point. Treatment, whether to cure or even arrest the fatal course, had been completely futile. The disease was *sui generis*, apparently a primary atrophy of the skin, and if the history and all the characters of the disease were considered, xeroderma pigmentosum could hardly be mistaken for any other affection.

Dr. Colcott Fox said that he saw the same three cases in 1882, when they were exhibited at a sister society as phases of lupus, and he claimed the credit of having pointed out their real nature on that occasion, and their special interest as examples of Hebra's Xeroderma. He was in possession of a water-colour drawing of the elder child, executed at that time, which showed the progress the disease had since made, and of sections of a growth, which displayed all the characters of rodent ulcer. As the time of the Society had expired, he would only mention one point in Dr. Crocker's paper, viz., the positive way in which he had described the affection as an atrophy. But, in truth, there was great divergence of opinion in this respect. Kaposi, indeed, suggested, and in this he was followed to a great extent by Neisser, that it began in atrophy of the papillary vessels, and that the pigmentation, teleangeiectasis, &c., were secondary, but Dr. Taylor, of New York, held strongly the opinion that it was primarily a new growth of vessels, and it might be truly said that so little had the early stages of the affection been worked out as yet, that no two observers were agreed as to the exact sequence of events.

The Society then adjourned.

CLINICAL SOCIETY OF LONDON.

Friday, March 14th, 1884.

Sir Andrew Clark, Bart., M.D., President, in the Chair.

The President announced that the Council had resolved to make a donation of twenty-five guineas to the Wheatley Memorial Fund, and expressed the hope that this contribution from the Society as a whole would not act as a check upon the generosity of individual members, but rather stimulate them to aid more effectually the objects of the Fund.

Multiple Hepatic Abscesses in a Boy.

Dr. Samuel West related the following case:—A Jewish lad, aged eleven, who had never lived out of London, had a rigor on January 21st, and pain in right hypochondrium. He was brought to the hospital on February 20th, with evident hepatic abscess, extremely ill, and temperature of 105°. On February 23rd, a large abscess aspirated, 13 ozs. of greenish sweet pus removed. Four days later, free incision, 7½ ozs. of turbid purulent fluid; a second abscess discovered and aspirated, 1 oz. of blood-stained pus removed. On March 6th, the two last swellings were again prominent, and were freely laid open, and a drainage-tube inserted. On April 9th, a fresh abscess was found, explored, and then freely laid open. From this time convalescence commenced, interrupted only by a diffuse abscess in abdominal walls, which healed on being opened and washed out. Points of the case:—1. The age, eleven years. 2. The number of abscesses, three or four, and probably more. 3. The absence of any assignable cause. 4. The great relief by evacuation. 5. The rapid fattening during convalescence.

Dr. Carrington thought that this case formed one of a group of which he had seen several examples at the Seamen's Hospital. He believed there was every reason to regard them as idiopathic, since in so many cases no primary cause for hepatic abscess could be discovered. In a case recorded by Dr. Goodhart, in the "Pathological Society's Transactions for 1881," the liver had been found studded with scars with caseous centres, apparently the result of a previous pylephlebitis, but proving the undoubted curability of such cases. The symptoms of hepatic abscess were not constant, but he laid stress on the importance of enlargement and local pain. Many other characteristic symptoms were as often absent as present. He mentioned a case in which high temperature, sweating, wasting, and enlarged liver had been found to be due to simple cirrhosis. He thought that a high temperature in cirrhosis was a more frequent occurrence than was usually supposed.

The President took exception to Dr. Carrington's statement as to the diagnostic value of pain and enlargement of the liver. He related particulars of cases in which the diagnosis of hepatic abscess had been made without the aid of special liver symptoms, and mentioned especially the value of local friction sounds in determining the local lesion when general symptoms of suppuration were present. In one case of single abscess thus diagnosed, no cause for suppuration could be found.

Dr. Cullimore, who had himself suffered from hepatic abscess, could fully corroborate the President's statement as to the occasional absence of pain and enlargement. In his own case the diagnosis had not been made until the abscess had burst through the lung. He would like to ask whether a large abscess could exist without any rise of temperature, and referred to a case in which, for a long time, no such rise had taken place. During one of the famines in India he had found abscesses in the livers of natives, who had died of starvation, without any evidence of intestinal or other lesions which might account for them.

Dr. J. K. Fowler referred to some observations, published by himself last year, clearly illustrating the possibility of diagnosing abscess of the liver from the stethoscopic signs of serous membrane inflammation. A case had lately occurred in which enlargement of the liver had been attended with sweating, pleuritis, and œdema of the superficial tissues, but no rise of temperature. Hepatic abscess was diagnosed, but the patient refused all operative treatment. The case ultimately proved to be one of amyloid disease, without abscess.

Dr. Mahomed referred to the clear distinction drawn between simple abscesses and those of pyæmic origin, and pointed out that the simple form was not of necessity large and single, although usually so. The term "multiple abscess" was usually employed to indicate the pyæmic variety. He mentioned a case admitted into the London Fever Hospital as enteric, but which proved to be pyæmic hepatic abscess. The patient had always shown a marked objection to lying down or to moving on the right side.

Dr. Percy Kidd related a case of hepatic abscesses in which no cause could be found *post-mortem*. Friction sounds had been heard at the base of the right lung. One of these abscesses was in the upper part of the right lobe behind, a second at the lower margin of the liver, and the third appeared to be burrowing round it.

The President called attention to the importance of observing the common seat of such abscesses, in order to determine the proper point for puncture. He believed that to puncture high up in the posterior axillary line was preferable to penetrating from before backwards.

Mr. R. W. Parker would ask Dr. West what positive proof had been present in his case, that the abscess had been in the liver at all. He mentioned a case which had closely simulated hepatic abscess, although due to burrowing of pus from an empyema between the liver and the diaphragm. He had since seen several cases of pus pent up in this situation.

Dr. White related particulars of a case, resembling gallstone colic, in which an abscess had been found, and successfully evacuated, in the left lobe of the liver. No cause whatever had been discovered for the suppuration.

Mr. R. J. Godlee advocated free opening of hepatic abscesses and careful antiseptic treatment. In the case of deep-seated abscesses, opened from behind, drainage might be established. Unless free relief were given to the pus

there was always a tendency to burrow through the liver tissue.

Mr. Henry Morris thought that all surgeons would agree in the propriety of giving free exit to the pus in such abscesses. He believed that as a general rule the cases in which openings were made through intercostal spaces were less successful than those opened below the lower margin of the thorax.

Mr. Golding Bird cited three cases in support of Mr. Morris's view.

Dr. S. West, in reply, thought that as regards the temperature in these cases it was probable that collections of pus might be present in the liver without fever, just as they occasionally occurred in other parts of the body. In his own case there had been marked fluctuation of temperature. He mentioned one of the last papers written by Dr. Murchison which dealt especially with hepatic intermittent fever. He had used the term "multiple" as descriptive; the case was certainly not pyæmic. He agreed with Mr. Morris as to the unsatisfactory results of tapping through an intercostal space. There could be no doubt as to the seat of the abscesses in his case.

Foreign Body in the Œsophagus—Œsophagotomy.

Mr. Butlin communicated the following case:—The patient, a man, aged 45, swallowed a gold plate, bearing four teeth, and having two long pins, during the night. The plate was impacted opposite the cricoid cartilage, where it produced serious spasmodic attacks of dyspnœa, and constant dysphagia. Since it could not be dislodged by means of forceps, &c., œsophagotomy was performed about twelve hours after it had become impacted. The plate was removed without difficulty; the patient progressed well during the first two days after the operation, then rapidly died of acute septic poisoning. Attention was particularly drawn to the difficulty of detecting the nature of an impacted body by sounding; to the difficulty of seizing the plate with forceps; to the results of swallowing fluids after the operation. It was contended that the unfortunate issue of this case ought not to influence the general rule of treatment in similar cases, namely, that œsophagotomy should be performed as early as possible after the impaction of the foreign body, if the body be hard and sharp, and it is evident that it cannot be removed by less formidable means. The cases of œsophagotomy for the removal of foreign bodies do not show a large mortality from septic poisoning; indeed, the reverse appears to be the case, for unless septic poisoning is produced by the presence of the foreign body, it has been rare as a result of the operation.

Mr. Harrison Cripps agreed that œsophagotomy had been the only treatment possible in this case. In cases, however, where the foreign body had become fixed lower down in the œsophagus, he thought that it would be advisable to push it into the stomach, the unrestricted passage of foreign bodies through the lower part of the alimentary canal being very commonly observed. He related the particulars of one case in which a large hair-pin had become fixed in the stomach, being subsequently extracted from the small abscess to which it had given rise.

Mr. Golding Bird thought it worthy of remark that so many of these cases, of accidental swallowing of foreign bodies, recovered. He gave the details of a case, in which, in less than an hour, a set of artificial teeth had passed down the œsophagus to the stomach. Being treated with thick oatmeal gruel, the patient ultimately evacuated the teeth per anum without trouble, but a small peri-œsophageal abscess ensued, probably as the result of injury inflicted by the plate in its passage downwards.

Dr. Glover advocated the use of emetics, and related a case in which a large piece of bone was successfully ejected from its position in the œsophagus by means of vomiting thus induced. In cases where swallowing was impossible, he would employ apomorphia subcutaneously.

Mr. Edmund Owen asked why the operation had been deferred for so many hours. He thought the use of emetics might, at times, be dangerous, as in a case lately seen in which artificial teeth had severely scraped the œsophagus in their downward passage, and were likely to do still further damage if violently ejected. He did not think that foreign bodies would be likely to stick in the œsophagus when once they had passed into the thoracic portion.

Dr. Duffin described an ingenious device adopted by Professor Syme for removing a fish-hook from the œsophagus, by striking off the barb.

The President referred to another case under Mr. Syme, in which a foreign body had penetrated the aorta.

Mr. Butlin, in reply, agreed with Mr. Golding Bird, that abscesses were liable to follow slight injuries to the œsophagus. He had delayed the operation in his case simply from want of room and of skilled assistance. It had been found that the gold plates used for artificial teeth might be easily broken if first treated with mercury, but the proceeding was hardly feasible when the plate was impacted in the œsophagus.

The following living specimens were exhibited:—Perforating ulcer of the foot by Mr. E. Owen; two cases of perforating ulcer, by Dr. Duckworth; congenital dislocation of patella, by Mr. Golding Bird; dislocation of patella, by Mr. Godlee; myxœdema, by Dr. James Anderson.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, March 5th, 1884.

H. Gervis, M.D., F.R.C.P., President, in the Chair.

Dr. Horrocks showed a wooden ring heavily coated with a deposit of lead from the use of lead lotions. It had been worn for five years.

Mr. Thornton showed a fibro-cystic myoma of the uterus, with both ovaries attached, removed from a single woman, aged 40. The patient recovered. Also a large fibroid uterus, with separate sub-peritonæal fibroids, small multiple cysts of the left ovary, and a large multi-occular tumour of the right ovary, with broad ligament cysts attached. The patient, aged 40, died of peritonitis on the fourth day.

Dr. Galabin showed (for Mr. Fielden, of the Chichester Infirmary), a cyst removed from the vulva, believed to be a hydrocele of a peritonæal pouch.

Dr. Heywood Smith showed a dermoid cyst of the right ovary, containing skin, teeth, bone, and hair. Also a large fibroid, removed together with the upper third of the uterus, from a woman, aged 39.

Dr. Boxall showed a morbidly adherent placenta, from a syphilitic patient, detached with great difficulty by the fingers. There were several accessory cotyledons joined to the main placenta by a membranous or velamentous inter-space of chorion. Also a placenta, containing a large blood cyst, nearly as large as an orange; the greater part of the fœtal surface being also occupied by old blood clot.

Dr. Barnes showed an ovarian tumour, removed at short notice on account of symptoms of twisted pedicle, viz., sudden access of severe pain, vomiting, and depression of pulse, together with rapid increase in the size of the tumour. The case showed that ovarian tumours should be removed as soon as diagnosed, in order to avoid the numerous accidents to which their owners were liable.

Corroding Ulcer of the Os Uteri.

Dr. Williams referred to the rarity of the disease, to the almost entire absence of any description of it in the systematic treatises on the diseases of women, and to the fact that its existence had been denied by some observers. The disease had been mistaken for cancer, and cancer had probably been mistaken for it. The histories of two cases, which had been under the author's observation for varying periods of time—one for two years and the other for about ten years—were narrated, and the *post-mortem* appearances, together with the microscopic characters of the ulcer in one

instance, were described. The differences between corroding ulcer, both clinical and anatomical, were pointed out, and the views of Sir Charles Clark, that the disease was distinct from cancer, upheld. The disease began at the os uteri, and extended along the vagina, involving the walls of that tissue in a symmetrical manner. Its progress was slow, and two of the author's patients died of their disease, while the third, who had been under observation for ten years, was still living. It was not associated necessarily with loss of flesh, and the pain and discharge were different from those usually met with in cancer of the uterus, and the edges of the ulcer were not hard and thickened. The mode of progress of the ulcer was in one case by means of reddish raised tubercles, which became ulcerated; in another, by slow ulceration, without any preceding change in the tissue about to be invaded, except some redness. The mucous surface to the edge of the ulcer appeared perfectly healthy. Microscopic examination showed this last observation to have been accurate, for the ulcer—its base and borders—presented no appearance, except that of granulation tissue. The case in which the disease presented the characters of lupus was still living. In the second case, which died, and which presented the miscroscopic appearances mentioned, the ulcer appeared to be the result of a slow gangrene, arising from calcification of the internal iliac arteries and their branches.

The PRESIDENT expressed his admiration of Dr. Williams paper, dealing so ably with a rare and interesting disease. He regretted that no autopsy had been allowed in the second case; but, from the results of the autopsy in the third case, the symptoms observed by the writer through a series of years in each case, and the observations of other authors, referred to by Dr. Williams, he thought that the disease must now be definitely withdrawn from the list of cancerous or cancroid affections. Dr. Williams' graphic description might have the effect of bringing cases, hitherto classed under the head of ulcerating epithelioma, under that of corroding ulcer.

Dr. PRIESTLEY said that the rarity of the affection was proved by the fact that some gynæcologists in large practice were doubtful if they had ever seen a case, and that its pathology was much disputed. Thus Kirvisch and Scanzoni regarded it as a variety of encephaloid cancer; Courty and West regarded it as a form of epithelioma. He thought he had seen the characteristic forms of the disease more than once. Sir Charles Clarke described the pain as burning, and not gnawing like that in cancer. He reminded Dr. Matthews Duncan of two cases which he had seen with him, in which a similar affection of the uterine body was not improbable without affection of the cervix. The symptoms were profuse, serous or mucopurulent discharge, with occasional hæmorrhage; the cavity of the womb was dilated, but there was no great enlargement of the organ. Both patients were advanced in age, the disease lasted for several years, death occurred from exhaustion, treatment had little effect. If he saw the disease on the cervix in an early stage, he should try the effect of various caustics. But treatment was not very promising.

Dr. MATTHEWS DUNCAN was deeply interested, for the disease had been the object of his special study for many years, and he believed it to be of the nature of lupus. He was not sure that he had ever seen a case identical with those of Dr. Williams, as to situation, but he had seen many in the lower vagina and external organs. Lupus of the external organs seemed to produce hypertrophies greater than any produced higher up in the passages. He had also seen the disease in the uterus, and one of the cases referred to by Dr. Priestley had been fully described by him in Vol. XXI. of the "Society's Transactions."

Dr. WILLIAM DUNCAN thought Dr. Williams' cases were lupus, which had taken on an epitheliomatous nature.

Dr. CHALMERS thought that the disease was not so rare as had been thought. He had seen two such cases in the last two years, in one case the patient died within a period specified in the prognosis given.

Dr. GALABIN asked Dr. Williams whether he regarded the disease as having any analogy with rodent ulcer of the skin, which was now regarded as a form of rodent cancer. It must either be lupus or a form of cancer in a wide sense. He had examined the uterus in Dr. Duncan's case, and found the deposit thickening the walls to consist of leucocytes, some of them having the suspicious character of being united by tailed processes.

Dr. GRIFFITH had seen a case which he thought similar. There was little pain, no glandular enlargement; it proved fatal in two or three years by repeated and uncontrollable hæmorrhage. No autopsy was allowed, but the left side of the uterus was felt much thickened.

Dr. ROUTH had seen two cases of the disease. There was no induration of surrounding parts, nor fixation of the cervix. The absence of induration made him dissent from the view that it was lupus. Moreover, the ulcer never healed, as it does sometimes for a time in lupus. He suspected a scrofulous or syphilitic taint acting on ill-fed and weakly persons. Similar ulcers had been described by Samuel Cooper. He thought there was some inconsistency in the author's statement that one case was analogous to senile gangrene and another to lupus.

Dr. AVELING said that Dr. Rigby believed that burning pain accompanying this form of ulceration was different from the darting pain of cancer. He asked Dr. Williams how far his observations agreed with this.

Dr. WILLIAMS replied that rodent ulcer was epithelioma, starting from hair follicles and sweat-glands, and corroding ulcer of the cervix could not be such. In one of his cases it appeared to be lupus, for the ring of tubercles with the cicatrix could be nothing else. This patient was still living, therefore no microscopical examination had been made. The third case was, in his opinion, senile gangrene, depending on calcification of the internal iliac arteries and their branches on both sides. He had used the word "malignant" loosely, as equivalent to incurable. He had seen one case of ulceration of the inner surface of the body of the uterus. The patient was over 60 years of age, had suffered long with offensive discharge, and was very fat. She died from other causes. At the autopsy the uterus was large, the walls thickened, the cavity large, secreting a quantity of broken-down dark material. Section of the walls showed nothing except the muscular fibres of the uterus rising to the surface, and in them many round cells, but nothing to indicate malignancy. No local treatment had been pursued.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, MARCH 3RD, 1884.

Mr. J. S. TURNER, M.R.C.S., L.D.S., President, in the Chair.

Defective Dentition.

MR. W. HERN showed models of three cases of defective dentition. The first, a boy, age seven, had only four teeth (molars) in the lower jaw, the alveolar ridge in front of these being narrow, and giving no evidence of the presence of any tooth germs. In the upper jaw he had six teeth, four molars and two conical teeth in the incisor region. Both the parents had their full complement of teeth, and so had a younger brother. In the other two cases, the canines were present as well as the molars, but the lateral incisors were absent, and the central small and ill-developed. Here, again, the parents had good teeth; and a younger brother had the proper number. Mr. Hern referred to some similar cases brought before the Society by Mr. Moon a few years ago, in which it was noticed that the elder children had defective dentition, whilst that of the younger children in the same families were normal.

Replantation.

Mr. CUNNINGHAM, of Cambridge, showed a patient for whom he had performed replantation. The tooth, an

upper central incisor, had been knocked out during a game at football, but the patient did not present himself until five hours after the accident. The alveolus was much lacerated, and the tooth very dirty; it was carefully cleansed, the pulp removed, and the nerve canal filled. It was then replaced and secured with silk ligatures. At the end of three weeks it had become quite firm, and was not to be distinguished from its neighbours.

Mr. ACKERY mentioned the case of a girl who applied to him on account of persistent hæmorrhage, following the extraction of a molar tooth sixty-two hours before. She brought the tooth with her, and Mr. Ackery, thinking it would make a capital plug, replaced it in its socket without removing the pulp or treating the canals. The bleeding was at once arrested, and when the patient came again a week later, the tooth was quite firm. She stated that there had been a little tenderness for a day or two, but this soon subsided, and the tooth had given her no pain since, so it was allowed to remain.

A discussion ensued as to how long a replanted tooth might be expected to last, supposing the immediate result to be satisfactory, the general opinion being that the average duration was from five to seven years, though instances of longer duration were to be met with, and that as the operation was not usually attended with much pain or inconvenience, the prospect of retaining a useful tooth for six years was quite sufficient to justify the experiment.

Hammond's Splint in the Treatment of Surgical Division of the Lower Jaw.

Mr. NEWLAND PEDLEY read notes of a case operated upon by Mr. Clement Lucas, at Guy's Hospital, for the removal of a sublingual epithelioma, in which the above-mentioned apparatus gave very satisfactory results. He pointed out that such cases were more difficult to treat than ordinary fractures, owing to the complete division of all the soft parts, and to the smooth surfaces of the cut ends of the bone.

Dental Jurisprudence.

A communication was read from Mr. F. R. LLOYD, of Mussoorie, North-West Provinces of India, relating a case which had been submitted for his decision. A gentleman's servant came to Lahore, saying that his master had been killed by savages while travelling in Kashgur, and that he had brought back his head. But Mr. Lloyd was able to decide, after careful examination of the teeth, that the head must have belonged to a much older man than the gentleman said to have been murdered, and further, that it was the head of a native, and not of a European.

GENERAL MEDICAL COUNCIL.

THIRTY-FIFTH SESSION.

FIRST DAY—MARCH 25TH, 1884.

New Member—President's Address—Election of Executive Committee—Pass and Pluck Statistics—Exceptional Cases—Personation at Examinations.

THE oligarchs who rule the medical profession, and watch over the Corporations, met for their thirty-fifth session, on Lady Day. A bleak March wind was blowing outside, and the Council chamber, which, when the session occurs later in the year, affords such a cool and pleasant retreat from the dust and glare of Oxford Street, struck a chill through every one who entered it. Even the Irish members felt it, and though restless, were more subdued than usual. The Council, indeed, seemed to feel the cold shadow of impending dissolution, and, from this point of view, the low temperature of the room was not inappropriate.

The first business was to receive into the fellowship of the Council, Professor Struthers, who has been appointed to represent the Universities of Edinburgh and Aberdeen. Like his predecessor, Professor Turner, Dr. Struthers is an anatomist, who has made valuable contributions to science, but in other respects the resemblance is not so striking, and it may be confidently expected that the wheels of the Council will not run less smoothly for the substitution.

The President, Dr. Acland, next delivered his usual inaugural address, which, under the circumstances, was shorter and less weighty than many that have preceded it. He alluded to the delay in medical legislation, extending now over fourteen years. It had been asserted that this delay had been owing to the action, or inaction, of the Medical Council; but history would show the contrary to be the fact. It must be admitted, however, that the persistent determination that no Bill, whether for the purpose of educational progress, or for the settlement of matters affecting the profession in its relations to the colonies or to foreign countries, should be permitted to pass, unless the Council were altered in its constitution, had practically produced the result of hampering that educational progress, and causing waste of time, suspense, and uncertainty in all existing medical schools, and in the examining boards. The time had come when they ought strenuously to endeavour, individually, if not collectively, to bring every influence to bear which might aid in settling medical legislation for some years to come, during the present session of Parliament; otherwise, there would be a continuance of unsettlement, misgiving, and agitation. The main principles of the Government Bill were four, viz.:—(1) To ensure one final pass examination in each branch of the kingdom, all three being reasonably uniform. (2) To appoint three medical boards which shall regulate the chief educational details, in the place of the branch councils. (3) To alter the mode of appointment of the supreme general council. (4) To amend or enact divers clauses which experience has shown to need revision or addition. It might be fairly assumed that the broad principles here laid down would not, with the present tendencies of political action in this country, be departed from. It seemed to him, therefore, that this Bill was the only way now known of quieting the disturbed state of education in the medical schools, and of getting into a reasonable and more uniform shape the increasing mass of knowledge which our students were required to produce at the examining boards. The President then alluded to the Medical and Dental Registers, and mentioned the statistics contained in them, which have already been quoted in these columns. He further spoke of the cases of Murray, Sadgrove, and O'Hara, which would come under the consideration of the Council, and concluded by stating that they would probably have to meet again for a short session in the summer, by which time it might be hoped that the Medical Bill would have been passed, and their new duties would have been clearly laid down. His own term of office would expire in the summer, and he would reserve till then his last expressions of gratitude and esteem.

The Council next proceeded to ballot for the Executive Committee. A few stray votes were scored by Mr. Marshall, Dr. Storrar, Dr. Matthews Duncan, Mr. Teale, and others, but nineteen of the members voted for the re-appointment of the old Committee in a body, and accordingly Sir Henry Pitman, Dr. Haldane, Dr. Humphry, Dr. Quain, Dr. Aquilla Smith, and Mr. Simon were declared duly elected.

The Pass and Pluck Statistics for 1883 of the various professional examinations were then presented to the Council. From these it appeared that in the first examinations taken together, 2,579 were passed, and 1,592 rejected; in the second, 815 were passed, and 424 rejected; and in the third, 2,700 were passed, and 1,102 rejected. The most difficult diplomas to obtain would seem to be the Mastership in Surgery of Durham University, and the licence under the new scheme of the Irish College of Surgeons. In the former examination, one passed, and eleven were plucked; in the latter, seventeen passed, and 100 were plucked; but, as Dr. Macnamara pointed out, these last figures are in all probability erroneous.

Before these returns were ordered to be entered on the minutes, Dr. Aquilla Smith gave some interesting comparative statistics, and showed that many of the examining boards were now rejecting twice, and even three times, as many candidates in proportion to those passed, as they had done in 1869. The chief exception to this rule occurred in the case of the Glasgow Faculty, which rejected 43 per

cent. of the candidates in 1883, against 44 per cent. in 1867. From these figures Dr. Smith inferred that the Corporations were now more alive to their responsibilities than they used to be, but the unprejudiced observer may possibly attribute the improvement on their part to a wholesome fear of impending legislation.

The next business before the Council was a table, containing the reports of the Corporations as to the number of exceptional cases, in which the requirements demanded of candidates had been modified. The English Colleges of Physicians and Surgeons, it appeared, had had respectively 26 and 22 such cases before them, all candidates from colonial and foreign schools; the other corporations had had to deal with comparatively few cases. A brief discussion arose on the subject, in which Dr. Macnamara laid himself open to the dry light of Sir Henry Pitman's facts, and the drier humour of Mr. Simon.

Certain communications in regard to the case of Arthur Augustus Sadgrove were then received, and ordered to be entered in the minutes, but the further consideration of this case was postponed.

A communication from the Provincial Medical Board of Nova Scotia gave the Rev. Dr. Haughton an opportunity of detailing his experience of preliminary examinations throughout the world, from which he had formed the bold generalisation that the Southern hemisphere—including Australia, New Zealand, and Ceylon, but not, apparently, South America—was farther advanced in preliminary education than the Northern hemisphere. He would hesitate, without further enquiry, to recognise the competency of the Provincial Medical Board of Nova Scotia to examine in mechanics and hydrostatics, and, indeed, he thought that medical boards generally knew nothing about those subjects. As, however, no one proposed to recognise the Nova Scotia examination, and as the general question of the competency of medical boards was not before the Council, the Rev. Dr. Haughton's remarks were merely the expression of pious opinions, and the Council passed on to the next business.

This was a letter from the Council's solicitor, stating that counsel had advised that "the offence of giving a false certificate of the cause of death, under Section 40 of the *Births and Deaths Registration Act*, 1874, was clearly a misdemeanour, and punishable by fine and imprisonment." After some discussion, the room was cleared of strangers in order that the Council might have the opportunity of hearing counsel's opinion read in full.

The Council next had before them the report of the Executive Committee on personation at preliminary examinations. In 1882 the Council decided that it was desirable that it should know what precautions are taken to prevent personation at the various preliminary examinations recognised by it, and it requested the Executive Committee to enquire into and report upon the matter. The Committee accordingly made enquiries and received replies from twenty-one bodies, after considering which they determined to recommend the Council to suggest to all examining authorities that, except so far as they may have in use other and better means of identifying candidates, precautions as follows should be taken—1. That each person desiring to present himself for examination by any examining authority should be required to make previous application to the authority in a prescribed form, signing his name to the application, and having his signature attested in a way which would suffice for its authentication. 2. That each examining authority should keep a signature-book for the candidates who present themselves for examination, each of whom should be required to sign his name in the book in the presence of an officer of the authority. The Committee also recommended that if the report were approved, copies of it, with the appended answers, should be sent to the several examining bodies concerned.

On the proposal to enter on the minutes the two recommendations of the Committee, the Rev. Dr. Haughton proposed to add a third, namely, "that the English language papers of each candidate who is examined be signed by him, and be preserved together with the before-named signatures for comparison, so far as may be necessary with his handwriting at subsequent examinations." Dr. Humphry and Mr. Simon, the movers of the resolution, expressed their willingness to accept Dr. Haughton's proposed addition, but Mr. Teale pointed out that the proposal would not work if the candidate went before another body for his subsequent examination.

After further remarks from Dr. Macnamara, Dr. Watson and Mr. Simon, the Rev. Dr. Haughton withdrew his proposal.

The two recommendations of the Committee were then ordered to be entered on the minutes, and the Council adjourned.

Second Day—March 26th.

The Cases of O'Hara, Murray, and Sadgrove—Personation at Examinations.

On Wednesday, the members of this august body resumed their labours with commendable punctuality. The first business was to decide whether the name of one Dr. O'Hara should be re-entered on the Register. He had already had his name replaced on the Register in Dublin. It appeared that in 1882, the name of Daniel Murray O'Hara, M.D., was struck off the Register, because no answer had been received from him, he being at the time resident in Australia. About the same time, the name of Owen Patrick O'Hare, M.D., was struck off the Register, as he had been convicted of felony. The question they had to decide, was whether the person who had been re-registered in Dublin as Dr. O'Hara, was really O'Hara, or as was suggested, whether he was the Dr. O'Hare who had been convicted of felony. The so-called Dr. D. M. O'Hara, had been summoned to appear before the Council, but instead he sent a medical certificate to the effect, that he was suffering from angina pectoris, and was not in a fit state to travel. A little diversion was created during the reading of this certificate, by one of the representatives from the sister isle taking objection to the President's mode of pronunciation of the word angina. The only real evidence, one way or the other in the case, was that of Mr. J. C. Needes, the medical agent. He had known Dr. O'Hare well in 1882, having transacted some business for him, and had then many opportunities for becoming familiar with his personal appearance. A week ago he had received a letter, dated from Prescott, from Dr. D. M. O'Hara, saying he wished to sell his practice in that town. That very morning, the said Dr. O'Hara, had called upon him about the sale of the practice, and he had at once recognised him as the same man, whom he had known in 1882, as Dr. O. P. O'Hare; on this point of the identity he was quite positive, the man whom he had seen that day was lame, and walked with a stick, just as Dr. O'Hare did in 1882. He produced the letter which he had received a week ago, and also some he had received in former times from Dr. O'Hare; in his opinion these letters were all written by the same hand, but in this view some of the Council did not concur.

O'Hare and O'Hara were fellow students at the same hospital, and both held the same diplomas, viz., M.R.C.S. Eng., and M.D.Q.U. Ire. As it appeared that before the name could have been replaced on the Irish Register, the diplomas must have been sent to the office, it was to be presumed that if the present man was O'Hare, and not O'Hara, he must, in some way, have possessed himself of the latter's certificates. As there was no other evidence forthcoming, the Council communed with themselves in privacy, and those who had the patience to wait during the full half hour that their deliberations lasted, were rewarded for their pains, by learning from the lips of the President on re-admission, that the Council had decided to decide nothing, until they were in possession of further evidence.

This business having been thus disposed of, the Council resumed the consideration of personation at examinations, and after a proposal by Dr. Patrick Heron Watson had been negatived, they accepted the resolutions put before them by the Executive Committee, as modified by Mr. Simon. The purport of these resolutions was, that every one desiring to present himself for examination should apply on a prescribed form, and have his signature duly attested; and that candidates, on presenting themselves for examination, should be called upon to sign their names in a book, and the two signatures could then be compared. Professor Humphry's

resolution, "That a copy of the above resolution, with the 'answers,' be sent to each of the several bodies, the certificates of which are accepted by the Council as satisfactory evidence of Preliminary Examination," was carried without opposition.

After a brief adjournment, the Council passed to Dental Business, and considered the report of the Dental Committee in the cases of J. P. Murray and A. A. Sadgrove. J. P. Murray had had his name erased from the Medical Register, for being engaged in kidnapping, and subsequently killing some Fiji islanders, and the British Dental Association requested that the facts should be considered by the Council, with a view to the erasure of the name from the Dentists' as well as the Medical Register. The offender had been announced to appear before the Council, on this day at four o'clock, but he failed to put in an appearance, and it was understood that he was far away in the wilds of Africa. The Council, therefore, proceeded to consider his case in private, and the room was again cleared of strangers. On their readmission, it was notified that the Council had judged J. P. Murray to have been guilty of infamous conduct in a professional respect, and had accordingly ordered his name to be erased from the Dentists' Register.

The Council then passed on to the case of A. A. Sadgrove, whose name had been erased from the Medical Register for falsely and fraudulently holding himself out to be a Licentiate of the Royal College of Physicians of London, and a Licentiate of the Royal College of Surgeons of Edinburgh. He had also been charged with unlawfully and willfully uttering a forged document, purporting to be a diploma of the Faculty of Physicians and Surgeons of Glasgow, and a long correspondence in connection with this charge was placed on the Council minutes for Tuesday last. The British Dental Association suggested to the Council that his name should also be erased from the Dentists' Register, while Sadgrove, on his side, had written to the Council, "not as a criminal, but as a gentleman who has been shown that only gentlemanly conduct will be tolerated in the profession to which he belongs," reminding the Council that "mercy rejoiceth against judgment," and begging that his name should be restored to the Medical Register. The Executive Committee, however, had remained deaf to his appeal, and informed him that they saw no reason to recommend the restoration of his name to the Register. These facts now (Wednesday) came within the cognisance of the Council, and Sadgrove appeared before it, and was heard in his defence. The case was considered *in camerâ*, and on strangers being readmitted, exactly the same resolution as had been passed in Murray's case was announced to have been passed *nomine mutato* in that of Sadgrove.

A rider to the Council's resolutions on personation at examinations was moved by Dr. STRUTHERS, and agreed to, viz.:—"That the various Examining Bodies be requested to intimate in future to the General Medical Council all cases of personation, with a view to the cases being communicated to the Examining Bodies recognised by the Council."

A communication from the College of Preceptors, containing a statement of the results of the preliminary examination, for medical students and others, held by the College on the 4th to 6th of September last, was read, and ordered to be entered in the minutes; the thanks of the Council being accorded to the College of Preceptors for the information contained therein; after which the Council adjourned.

THIRD DAY—MARCH 27TH.

Dental Business—Funeral of Dr. A. Thomson—The Colleges and the Conjoint Scheme—Unqualified Assistants—International Congress—Finance and Pharmacopœia Committees—Preliminary Examinations.

Business was opened punctually by the reception of a report on dental business, showing the results of examinations held under the Dentists' Act during 1883; 86 candidates had passed, against 19 plucked, a large number of diplomas still being conferred by the Irish College of Surgeons, without curriculum. Reference was made by the President to the death of Dr. Allen Thomson, and he suggested that a deputation from the Council should attend the funeral at Euston station during the afternoon. The proposal was unanimously adopted, and three members representing the three divisions of the Kingdom, were at once requested to carry it out. On their return from paying this mark of respect to the late Professor, the President of the College of Surgeons spoke feelingly of the scene just witnessed.

On a motion to receive upon the minutes two letters from the Colleges of Physicians and Surgeons respectively, withdrawing from the Conjoint Scheme of 1877, a long discussion took place, upon a suggestion, emanating from Dr. Quain that before accepting these letters some explanation should be demanded from these and other corporations as to the reason why the Conjoint Scheme had never been put in force. It was made clear by the President and others that the Conjoint Scheme itself fully provided that any of the parties thereto might at any time withdraw from it on giving due notice. Ultimately a resolution was carried by the Rev. Dr. Haughton, under which the question was postponed till the following day, not without some protest on the part of Sir H. Pitman and others, to whom the reopening of the subject of the Conjoint Scheme appeared neither germane to the question nor desirable in itself.

Two letters from the Privy Council Office and from the General Register Office respectively, in reply to the communication of the Council of May 14th, 1883, on the subject of unqualified assistants and their irregularities, were received, and a suggestion conveyed from the Registrar-General that the Council should formulate a clause upon the subject for insertion in the Medical Acts Amendment Bill, was deferred for future discussion. A letter from the Science and Art Department, at South Kensington, with reference to the appointment of a delegate to attend the Congresses at Copenhagen and the Hague, was received without comment.

The report of the Finance Committee, showing a very flourishing state of accounts, was adopted. The excess of income over expenditure during the past year amounted to 3,494*l.* 1*s.* 0*d.*, as against an excess during 1882 of 2,343*l.* 17*s.* 10*d.* In proposing the adoption of the report of the Pharmacopœia Committee, Dr. Quain took occasion to make a suggestion, which was eventually agreed to by the Council, that the fees and expenses of the members required to attend special meetings of the Committee should be paid by the Treasurer. Upon a report of the Preliminary Examinations Committee, in reply to a letter from St. Thomas's Hospital calling attention to the frequent evasion of one of the regulations, a long discussion took place, in which two important points were raised. The subject of elementary mechanics, would appear to be frequently avoided by candidates for registration, owing to the fact that under existing rules, it is left open to them to take the subject up at any future period of their medical career, after the preliminary examination. In England, however, it was clearly shown, that no facilities exist for examination in the one subject alone, although, according to the Irish and Scotch representatives, the difficulty is avoided in their respective schools by the different systems of examination. The Registrar pointed out that he had no means of telling whether the regulation had been complied with in every case, nor were the branch registrars in any better position. An expression of opinion by Dr. Matthews Duncan, that some rule should be made to meet the apparent failure of the existing plan in England, did not meet with so much favour as a proposal by Sir Henry Pitman, supported by the President and many other speakers, to enforce the present rule as it stands. The importance of the subject of mechanics and hydrostatics was insisted upon by Mr. Simon, but he clearly showed that, while a good knowledge of it was essential to the practitioner of medicine, it was less important to the commencing student. The possibility of a speedy dissolution of the Council, referred to in the Report was somewhat severely descanted upon by various members, of whom many, and especially those from the Sister Isle, expressed neither fear nor apprehension that their present labours were likely to be rendered null and void by any approaching legislation.

The subject of preliminary education in general was deferred for further discussion on the motion of the Rev. Dr. Haughton.

OBITUARY.

JOHN HALL DAVIS, M.D. Lond, F.R.C.P. Lond.

In Dr. Hall Davis, whose death occurred suddenly on Wednesday week, the obstetric branch of the profession in London has lost one of its most prominent and most highly respected members. He was not by any means advanced in years, and had only just resigned his post of Obstetric Physician to the Middlesex Hospital. He received his medical education at University College, and graduated as M.D. at the London University in 1845, the year after Sir W. Jenner, and the year before Sir W. Gull took the same degree. He became a member of the Royal College of Physicians in 1851, and soon after was appointed Physician to the Royal Maternity Charity, a post he held for over thirty years. Later on he was elected a Fellow of the Royal College of Physicians, and appointed Obstetric Physician and Lecturer on Obstetric Medicine to the Middlesex Hospital. He was one of the earliest Presidents of the Obstetrical Society, and held office during 1867-68, at the time of the Baker-Brown controversy. He devoted his attention more to midwifery than to gynæcology, and published contributions on "Puerperal Convulsion," and "Chorea complicating Pregnancy." Dr. Hall Davis was a man of high personal character, and of sound judgment, with a thorough knowledge of his profession and his own specialty. He was of an amiable and conciliatory disposition, had many friends and no enemies. He was not highly endowed with energy or originality, but he has left behind him an example of honest and quiet work, unstained by the jealousies and rivalries that so often go hand-in-hand with higher attainments.

ALLEN THOMSON, M.D., LL.D., F.R.S. Ld. and Ed.

In the fulness of years has passed away one who was, perhaps, the centre of more affectionate regard than any other member of our profession. Allen Thomson was born in Edinburgh in 1809, the son of Dr. John Thomson, who was Professor of Surgery in the Edinburgh University, and a man of great power and culture. His maternal grandfather was Prof. John Millar of Glasgow, a well-known writer on constitutional law. Allen Thomson received his early education at the High School, and his medical education at the University of Edinburgh. He subsequently studied at Paris, but returned to Edinburgh to take his M.D. degree in 1830. The next year he was elected a Fellow of the Royal Society of Edinburgh, and, in association with Dr. Sharpey, began to lecture on the Institutes of Medicine in the Extra-Mural School. He had already entered upon the embryological studies, in which he afterwards made his name, and contributed some valuable papers connected with this subject to the *Edinburgh New Philosophical Journal* in the same year that he took his degree. On the removal of Dr. Sharpey to London in 1836, Dr. Thomson began to lecture in the Extra-Mural School on Anatomy, and continued this work until he accepted the Professorship of Anatomy at Marischal College, Aberdeen. This post he filled for three years. He was then recalled to Edinburgh to take the place of Dr Alison as Professor of the Institutes of Medicine in the University, and six years afterwards, in 1848, he was appointed by the Crown to the Chair of Anatomy at Glasgow. This chair he held until 1877, when he finally retired from active life, and took up his residence in London. He served at various times as councillor, vice-president, and president of the Glasgow Philosophical Society; and from 1859 to 1877 represented the Universities of Glasgow and St. Andrews on the General Medical Council. The degree of LL.D. was bestowed on him by the University of Edinburgh in 1871; and by that of Glasgow in 1877; while in 1882 the University of Oxford conferred the corresponding distinction of D.C.L. At the Edinburgh meeting, in 1871, of the British Association, Professor Thomson presided over the Biological Section, and in his address took occasion to make an attack on spiritualism, which gave rise to some lively discussion. At the Glasgow meeting, in 1876, he was one of the vice-presidents, and the Plymouth meeting, in 1877 found him in the distinguished position of President of the Association. The address, he delivered on that occasion was devoted to an exposition of the gradual acceptance of the Darwinian theory, and was regarded on all sides as a most able contribution to current thought. Since 1877, Dr. Thomson has been a well-known and much welcomed figure in the scientific societies of the metropolis, and his counsel has been freely sought in many matters connected with his own branch of study, especially in regard to the appointment of anatomical lecturers in all parts of the country.

Dr. Thomson was great, both as a teacher and as an investigator. In the former capacity, he was always successful in securing the respectful attention, and in many cases the devoted attachment, of his pupils. As a writer, he was not copious, but his contributions to science were of great importance. The chief results of his work are to be found in an article on the "Early Stages in the Development of the Human Embryo," published in the *Edinburgh Medical and Surgical Journal*; in a paper on "The Origin of Double Monsters," in the *Edinburgh Monthly Journal of Medical Science*; in the articles, "Circulation," "Generation," and "Ovaries," in "Todd's Cyclopædia of Anatomy;" in various articles in the *Encyclopædia Britannica*; and in a series of papers communicated to the Royal Society. He was one of the editors of the sixth, seventh, eighth, and ninth editions of "Quain's and Sharpey's Anatomy."

A man of liberal thought, and wide culture, of most generous and sympathetic disposition, and with a power of influencing his fellows possessed by a few, Allen Thomson possessed an individuality which will long make him remembered by all who knew him.

GENERAL CORRESPONDENCE.

SHIP-SURGEONS.

[To the Editor of the Medical Times.]

Sir,—I am glad to find from a letter in your impression of Saturday last, as well as from several communications I have received, that the suggestions I made in the columns of *The Times*, of December 24th, that ship-surgeons should enrol themselves into a Mercantile Marine Service, meets with the approval and staunch support of ship-surgeons in general. I would advise your correspondent, who writes from Port Said, and others interested in the scheme, to place themselves in communication with Dr. Irvine, whose name is intimately associated with the movement, and lay their grievances before Parliament. Now is the appointed hour, "they must take the current as it serves, or lose their ventures," always remembering that "that work which is begun well, is half done," and that "opportunities, like clouds, pass away." The question might very well form part and parcel of the Merchant Shipping Act now before the House of Commons, a few of the shortcomings of which I have pointed out in a lengthy paper in your contemporary, *Land and Water*, of Saturday, March 22nd. In conclusion, allow me to reiterate the statement, that superintendents of mercantile marine do not always require a ship-surgeon to produce evidence of possessing legal qualifications. If necessary, I am prepared to adduce facts, the veracity of which cannot be impugned, corroborative of my assertion.

I am, Sir, Yours, &c.,

W. DOMETT STONE, M.D.

19, *Oxford Terrace, Hyde Park, W.*

SNAKE POISON.

[To the Editor of the Medical Times.]

Sir,—Permit me to say in reference to Sir Joseph Fayrer's statement, at page 146 of the current volume of this journal, that snake poison cannot be swallowed with impunity, which he says is contrary to *all former and universal belief*; that

nearly forty years ago, when speaking in this same periodical of a sect of African poisoners, among the slaves in this country, I mentioned the venoms of the serpent and of the toad, as amongst their most deadly arms. All the population of San Paulo, a country as extensive as France and England united, has known from time immemorial that snake poison taken into the stomach *kills*. In Africa also this must be known, as evidenced by the practices of the Feitiçeiros (Feitisseiros) or poisoners. This is far from being the first occasion when I have seen ignored statements of fact, or suggestions, contained in my letters to the *Medical Times*, of which the first bore date (*salvo errore*) of 1843.

I am, Sir, Yours, &c.,

RICHARD GUMBLETON DAUNT, M.D. Edin.

Campinas, San Paulo, Brazil.
February 27th, 1884.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the Fellows and Members of the College was held on Monday last.

The PRESIDENT, after taking the chair, briefly explained the objects for which the meeting had been summoned, viz., to sanction principles rather than lay down in definite terms the particular form which certain proposed alterations in their Charters should assume: this latter point would have to be determined by their legal advisers. After the printed proposals had been disposed of, it would be open to members to make any further suggestions, provided always they had reference to the Charters.

The first alteration proposed was in the Section of the Charter of George IV., which restricts the amount of property in lands or rents to be held by the College to 2,000*l*. The Council now advise that this amount be increased to 10,000*l*. This was carried after a short discussion, which turned on the advisability of still further increasing the amount. The President pointed out that a definite sum must be mentioned, and that it ought not to be too large.

It was next proposed that Section 5 of the Charter of the 7th Victoria be altered, so as to provide that the conditions of admission to the Fellowship by examination, and the arrangements for the examinations, be in future determined by resolutions of the Council, instead of by by-laws.

The PRESIDENT, in answer to a call, explained that at present any proposed changes in these examinations could only be carried out after considerable delay, and after appeal to, and with the sanction of, the Privy Council, and that the hands of the Council were thus much tied. As regarded the examination for Membership, they held the necessary power, and he (the President) thought that if the Council could be trusted in this matter, which was of great moment to the public welfare, they might also be trusted in the lesser matter of the Fellowship examination, which was largely an ornamental diploma, and not merely a licence to practise.

Mr TWEEDY proposed an amendment to the effect, that the proposed changes would tend to the relaxation of the conditions of admission to this examination, which was not expedient. In speaking to the motion, he argued the greater expenditure in time, money, and trouble, which the Fellowship, as at present regulated, required of those who aspired to it, and he thought it would be unjust on those who had obtained it, if the present conditions were lowered or relaxed. He referred to the high standing which the Fellowship of the English College had attained, in comparison with that of Edinburgh, owing to the manner in which the latter was trafficked for. He argued that there had constantly been a tendency on the part of the authorities to lessen the standard required of those who sought the higher diploma, with a view to increase the number of the Fellows, and he deprecated the granting of any facilities for this purpose. He referred more especially to the conditions which regulated previous study and the general culture of candidates, and not to the later examinations, which, if anything, were too hard, and appeared designed to get at what a man knew rather than at what he could do in practice. If the Council, he said, had been able to effect these changes, the by-laws notwithstanding, what would they not be able to accomplish, when the by-laws were abrogated. His wish was that they should not have the power to constantly change the conditions, but that these should stand fast. Mr. Tweedy instanced examples of recommendations of Council not being carried out, and he argued herefrom the undesirability of giving the Council the power of altering at will the requirements of so important a point as the Fellowship examination.

The PRESIDENT (somewhat contrary to the established custom of public meetings) answered Mr. Tweedy's remarks in some detail and with some warmth; he deprecated the idea that the Council would ever use any additional power they might acquire for any other purpose than to keep up and increase the dignity of the Fellows. In reference to the question of the non-carrying out of the recommendations of Council, referred to by Mr. Tweedy, he said that to have done so would have been contrary to the Charters of the College.

After a little passage of arms between some provincial Fellows and the President, on the point of the Council sometimes passing resolutions which were contrary to the Charters, Mr. Tweedy's amendment was put to the meeting. It was lost by two votes; and the Council's proposal was after a little further discussion passed.

The third proposal was that, in Section 7 of the Charter of the 7th Victoria, the amount of the fee for the Fellowship by examination be omitted, leaving such amount to be provided for by by-law. The real object was, to enable the Council to raise the fee in proportion to the greater expense entailed on the College by the more extended examination now enforced. This passed unanimously, as soon as its object was explained to the meeting.

The fourth proposal brought forward had reference to the mode of election to the Council. In past times Fellows have only been able to vote in person, and it is now proposed to give them the power of proxy voting. It is needless to say that the proposal met with a hearty reception, and was unanimously passed. The Association of Fellows put in a resolution to the effect, "that the concessions announced by the Council include all the objects for which the Association has contended."

The next proposal was, that it was undesirable that members of twenty years' standing, on election to the Fellowship, should pay a fee. This also was carried.

The sixth recommendation, to abolish the diploma of Licentiate in Midwifery, was put and carried.

The seventh and last of the Council's recommendations concerned the dental qualification; they sought for powers to increase the numbers of examiners in dental surgery, and to insist on registration as a qualification for examiners. The resolution was passed.

The PRESIDENT then stated that he would be glad to put to the meeting any other recommendations which Fellows or Members present might wish to have discussed, provided always the recommendations applied to the Charters of the College.

Mr. SWAIN, thereupon, moved "That in the opinion of this meeting, it will materially conduce to the future welfare of this College that the Fellows [and Members] should be invested with a larger share in its management; and (2) that it is desirable that no alteration in the constitution and relations of the College be effected without the consent of the Fellows [and Members] convened to discuss such alterations; (3) further, that there shall be an annual meeting of the Fellows [and Members], at which the annual report of the Council shall be submitted, received, and adopted, and that at such meeting the President for the ensuing year be elected by the majority of Fellows then present, and that the Charters be so altered as to give this resolution effect."

Mr. OLIVER PEMBERTON seconded the resolution. The words in brackets were accepted by Mr. Swain, and subsequently added to the resolution, which was unanimously carried.

Mr. Hickman proposed, "That powers by Charter be applied for to enable the College of Surgeons and of Physicians to combine, and grant a joint diploma of Doctor in Medicine, and Master in Surgery." He pointed out, how in Scotland an examination, of no greater severity than that required by the Colleges in London, gave the much coveted title of Doctor, and he believed that the granting of a similar title in London would strengthen the hands of the Colleges. Many English students now went to Scotland, who would otherwise study in London, and affiliate themselves with the English Corporations.

Mr. Hardy seconded the resolution, which was carried.

Mr. Charles Hawkins proposed a vote of thanks to the President for his services in the Chair; he paid a just tribute to the firmness, impartiality and kindness with which his arduous duties on this occasion had been discharged.

Mr. Wheelhouse seconded the motion, which was carried by acclamation.

After a few words of acknowledgment from the President, the meeting broke up.

Royal College of Surgeons.—The library of the Royal College of Surgeons will be closed on Monday next, for the purposes of the examinations.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 20, 1884:—

Cropley, Alfred, Swaton, Lincolnshire.
Evers, Chas. Jno., Kidderminster Street, Stourbridge.
Harris, Arthur Wellesley, Exmouth Street, W.C.
Jefferies, Horace, Bromsgrove.
Long, Edwin Walter, Southsea.
Morris, Rich. Jno., Thornton, Bradford.
Reeks, Jno., Elvin House, Andover.
Smith, Stephen Fras., Holloway Road, N.
Stephenson, Sydney Harry, Clerk Street, Edinburgh.
Walker, Harry Victor, Walker Terrace, Plymouth.

The following gentlemen also, on the same day, passed their Primary Professional Examination:—

Baronoff, Paronnag-Jean, Lariboisière, Paris.
Thorpe, George, of St. Bartholomew's Hospital.

Naval Medical Department.—The following appointments have been announced:—Deputy-Inspectors-General of Hospitals and Fleets—John Fisher, to Hong Kong Hospital, *vice* Gordon; Doyle M. Shaw, C.B., to Plymouth Hospital, *vice* Fisher. Surgeons—Robert H. Nicholson, to the *Albacore*, *vice* Armstrong; William Hayes, to the *Royal Adelaide*, *vice* Nicholson; J. F. Donovan, M.D., to the *Duncan*, *vice* McAdam; Charles James and Robert W. Doyne, to the *Temeraire*, recommissioned; Fleet-Surgeon George Bolster, to the *Alexandra*, recommissioned.

General Medical Council.—The President, Dr. Acland, C.B., F.R.S., entertained a party of members and friends at breakfast at Limmer's Hotel on the 25th instant. There were present:—Sir James Paget, Bart.; Sir Henry Pitman; Professor Struthers; Professor Huxley; Professor Humphry, M.D.; Sir Joseph Fayrer, C.B., K.C.S.I.; Dr. T. K. Chambers; Dr. Banks; Dr. Matthews Duncan; Dr. T. D. Acland; Rev. Dr. Haughton; Dr. Watson; Dr. Haldane; Dr. Petigrew; Dr. Aquilla Smith; Dr. Pyle; Sir Thomas D. Acland, M.P.; Mr. A. D. Acland; Mr. Griffiths; Mr. J. C. Miller; Dr. R. Macnamara; Mr. Arthur Mills; Mr. R. B. D. Acland; Mr. T. Pridgin Teale; Mr. T. Collins; Mr. J. Marshall; Mr. Edward Bradford, and Sir J. Risdon Bennett.

University of Edinburgh.—The various classes in the Medical Faculty of the University of Edinburgh were brought to a close, on Friday the 21st instant, when the different Professors presented the class medals, prizes, and certificates to the successful students. In few cases were formal addresses delivered. On Thursday, Professor Annandale, in bringing his clinical surgery class to an end, offered some remarks to the students on the desirability of their having increased opportunities of carrying on practical work, for under the present state of things, he said, a student might pass all the examinations necessary for obtaining the medical degree, and yet be very deficient in the matter of practical knowledge. With the view of remedying matters, it had been arranged that Professor Chiene's students should have a break in their course of lectures in the middle of each week, so as to enable them to devote more time to clinical work.

The Association of Surgeons Practising Dental Surgery.—This association has just instituted a Cartwright Medal, in honour of its president, Mr. Samuel Cartwright, F.R.C.S., to be awarded either biennially or triennially, for the best essay on dental surgery, scientific or otherwise, and to be competed for by registrable medical practitioners. We feel sure there are many who may feel disposed to subscribe for such a purpose, knowing the high esteem in which Mr. Cartwright is held in the profession at large. Subscriptions or donations will be received and duly acknowledged by Mr. Hamilton Craigie at 13, Savile Row, London, W. The first three trustees of the fund are Messrs. F. B. Imlach (Edinburgh), S. H. Cartwright, and J. H. Craigie.

National Hospital for the Paralysed and Epileptic.—The meeting, under the presidency of the Lord Mayor, recently held at the Mansion House, in aid of funds for rebuilding this hospital, resulted in contributions to the amount of 1,500*l*.

York Lunatic Asylum.—At the Annual Court of Governors, held on March 18th, the report showed a satisfactory state. Improvements had been, and were being effected in the ladies' galleries, and additional means of escape in case of fire were in course of construction. The sewers had all been cut off from the city drains, and ventilating shafts had been erected, the pipes from which discharged on to open gratings. The health of the patients was good; and the Commissioners, at their last visit, had reported that they found the institution in first-class condition.

Inebriety.—On the 25th ult., at a meeting of medical men held in London, a new association, entitled "The Society for the Study and Cure of Inebriety," was formed, to investigate, from a scientific standpoint, the various causes of inebriety, and to educate the professional and public mind to a knowledge of these causes, and a recognition of the physical aspect of habitual intemperance. The officers for the first year are:—President, Dr. Norman Kerr. Vice-Presidents, Sir Geo. Burrows, Bart.; Sir Spencer Wells, Bart.; Sir Geo. H. Porter, Dublin; Sir Edwin Saunders; Sir Wm. Miller, Londonderry; Dr. W. B. Carpenter, F.R.S.; Dr. Cameron, M.P.; Dr. Farquharson, M.P.; Prof. Maclagan, Edinburgh; Dr. B. W. Richardson, F.R.S.; Dr. J. S. Bristowe, F.R.S.; Prof. Macalister, Cambridge; Prof. McKendrick, Glasgow; and Dr. C. J. Hare. Treasurer, Dr. C. R. Drysdale. Secretary, Dr. J. M. Caw. Council, Dr. Alfred Carpenter, J.P.; Dr. Joseph Eastwood, J.P.; Dr. Balding, Royston; Surgeon-General Francis; Surgeon-Major Evatt; Surgeon-Major Poole; Dr. Hart Vinen; Dr. Danford Thomas; Dr. Haynes, Malvern; Dr. Wickham Barnes; Dr. Sibley Hicks, Liverpool; Dr. Hurry; Dr. Geo. Robertson; Dr. Smith, Rickmansworth; Dr. Bridgewater, Harrow; Dr. Branthwaite, Willesden; Dr. Murray Lindsay, Derby; Dr. Alex. Peddie, Edinburgh.

Charitable Bequests.—The Baroness Lionel de Rothschild has bequeathed large sums to medical and general charities, amongst the former 10,000*l*. to the London Hospital, Whitechapel-road; Evelina Hospital, Southwark, 10,000*l*.; West London Hospital, Hammersmith, 3,000*l*.; Jews Hospital, 3,000*l*.; Jewish Convalescent Home, 2,000*l*.; German Hospital, 2,000*l*.; Metropolitan Free Hospital, 2,000*l*.; Buckinghamshire Hospital, Aylesbury, 1,000*l*.; Royal Sea-Bathing Infirmary, Margate, 1,000*l*.; Royal Hospital for Incurables, Putney, 1,000*l*.; Earlswood Asylum for Idiots, 1,000*l*.; and St. George's Hospital, 500*l*. Sir William H. Poland, formerly of Blackheath, has bequeathed 50*l*. each to the Earlswood Asylum for Idiots, the Royal Hospital for Incurables, Putney, and the Royal Kent Dispensary, and nineteen guineas to the London Hospital for Diseases of the Heart, Soho-square.

Earlswood Asylum for Idiots.—This institution has been very fortunate during the past week in the amount of legacies left to it, as in addition to the above-named, Mrs. Mary Ann Ellis, late of York, has bequeated 500*l*. in aid of its funds.

THE ADULTERATION OF DAIRY PRODUCTS.—A Committee of the New York Senate has reported the results of an enquiry into the adulteration of dairy products. Of thirty samples of butter two-thirds were only remotely traceable to milk. The refuse fat of pigs and bullocks was the chief and most savoury ingredient, but often spoiled greases were used which had been deodorised by nitric and sulphuric acids. The material was also found to contain ingredients which are fatal to infants. The doctors, who were examined upon oath, declared that the consumption of this compound had a distinct bearing upon the death-rate. The Committee advises the total prohibition of the manufacture of oleomargarine. The interest in this subject is not confined to the United States, as the exports in February included nearly one million pounds of butter, and over three millions of cheese.

THE OPERATIONS ON THE RED SEA.—It must be very gratifying to the medical department of the army, to see how well the war correspondents of our daily papers speak of the medical officers marching to Suakin. It is impossible, says the *Daily News*, to praise too highly the efficiency of the medical department. There are excellent arrangements for the conveyance of large quantities of ice from the fleet to the camp for the use of the sick. The heat is described as so intense that numbers of the men fell out quite exhausted, in some cases it was necessary, but it was unpleasant to hear the medical officers, who patiently bore the heat so well, call out sharply to the laggards "Double, double! I will have you court-martialled; do you want to lie there and be assegaied?" Some men, he adds, he could see were shamming.

APPOINTMENTS.

BRAND, A. T., B.M.M.C. Aber.—Medical Officer to the Workhouse and the Driffield District, Driffield Union.

COXWELL, C. F., M.R.C.P.—Assistant Physician to the Royal Hospital for Diseases of the Chest, City Road, *vice* Gabbett, resigned.

DRUMMOND, ALEXANDER P., M.D.—Medical Officer for the parish of Prestonpans, *vice* Jas. B. Cunningham.

ELLIS, R., F.R.C.S.—Honorary Consulting Surgeon to the Sheffield and South Yorkshire Ear and Throat Hospital.

ERSKINE, J., M.A., M.B., C.M.—Assistant Surgeon to the Glasgow Hospital and Dispensary for the Diseases of the Ear.

FREER, E. L., M.R.C.S.—Honorary Surgeon to the Birmingham Orthopædic and Spinal Hospital, Birmingham.

FREER, W. C., M.R.C.S.—Consulting Surgeon to the Birmingham Orthopædic and Spinal Hospital, Birmingham.

GARMAN, W., M.B., C.M.—Resident Physician to the Queen's Hospital, Birmingham, *vice* Dr. Sanders, resigned.

GOULD, A. P., F.R.C.S., B.Sc. Lond.—Surgeon to the Royal Hospital for Diseases of the Chest, City Road, *vice* Walsham, resigned.

LOVE, J. H., M.R.C.S., L.S.A.—Medical Officer to the First District, Wolverhampton Union.

MACPHERSON, R., M.B., C.M.—Physician on the Staff of Anderson's College Dispensary, Glasgow.

OLIPHANT, E. H. L., M.B., C.M.—House Surgeon to the Glasgow Maternity Hospital, Glasgow.

RICHARDSON, H. E., L.R.C.P., L.R.C.S.—Senior House Surgeon to the Borough Hospital, Birkenhead, *vice* M. Bernstein, M.B., resigned.

RIVINGTON, WALTER, F.R.C.S.—Lecturer on Surgery at the London Hospital Medical School.

SPICER, R. H., M.R.C.S. Eng., L.S.A.—Medical Superintendent of the Infirmary, Fulham Union.

SUNDERLAND, S., M.D., L.R.C.P., M.R.C.S.—Resident Medical Officer to the Royal Hospital for Children and Women, Waterloo Bridge Road, S.E., *vice* J. F. Briscoe, M.R.C.S., resigned.

TREVES, FREDERICK, F.R.C.S.—Lecturer on Anatomy at the London Hospital Medical School.

WHITAKER, J., M.B., M.C. Edin.—Medical Officer to the Westhoughton District, Bolton Union.

WILSON, ALEX., M.R.C.S., L.R.C.P.—Junior Resident Medical Officer to the General Hospital for Sick Children, Pendlebury, Manchester.

VACANCIES.

ALSTON WITT GARRIGILL PARISH.—Medical Officer for the Second District, in succession to Dr. A. J. Pickworth, resigned. Area, 24,000 acres. Population, 2,333. Salary, £8 per annum.

BRIGHTON AND HOVE LYING-IN INSTITUTION.—House Surgeon. Salary, £120 per annum, with furnished apartments, coals, gas, and attendance. Candidates must be members of one of the Royal Colleges of Surgeons of Great Britain and Ireland, and Licentiates of the Royal College of Physicians of London, or of the Apothecaries' Company in London, duly registered under the Medical Act, unmarried, and under 30 years of age. Diplomas, testimonials, and copy of registration to be forwarded to the Secretary, before April 4th. The election will take place on Friday, May 2nd.

DEPWADE UNION.—Medical Officer for the Second District, in succession to Mr. J. L. Currie, resigned. Area, 5,489 acres. Population, 1,092. Salary, £39 per annum.

FLINTSHIRE DISPENSARY.—House Surgeon. Salary, £100 per annum, with furnished house, &c. Candidates' names must appear on the Medical Register, as being possessed of Medical and Surgical qualifications, and they must produce evidence of good moral character. Private practice prohibited. Candidates conversant with the Welsh language preferred. Applications, with testimonials, to be sent to the Secretary, on or before April 15th. The election will take place on April 30th.

GREAT NORTHERN CENTRAL HOSPITAL, CALEDONIAN ROAD, N.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)

JARROW PROVIDENT DISPENSARY.—Qualified Practitioner. (*For particulars see Advertisement.*)

MORPETH DISPENSARY.—Resident Medical Officer. Salary, £100 per annum, with furnished apartments, coals, and gas. Candidates must be duly qualified, and unmarried. Applications and testimonials to be sent to Mr. D. W. Greenwood, Morpeth, on or before April 5th.

NEWPORT PAGNELL UNION.—Medical Officer for the Fifth District, in succession to Mr. Deyns, resigned. Area, 16,286 acres. Population, 5,749. Salary, £65 per annum.

ORTHOPÆDIC AND SPINAL HOSPITAL, BIRMINGHAM.—Honorary Assistant Surgeon. (*For particulars see Advertisement.*)

SPILSBY UNION.—Medical Officer for the Strickney District, in succession to Mr. Grimoldsby, resigned. Area, 11,518 acres. Population, 2,112. Salary, £46 per annum.

STOURBRIDGE UNION.—Medical Officer for the Kingswinsford District, in succession to Mr. G. Ashmead, resigned. Salary, £50 per annum.

WEST LONDON HOSPITAL, HAMMERSMITH.—Surgeon. Candidates must be Fellows of one of the Royal Colleges of Surgeons of London, Edinburgh, or Dublin, and not practising Midwifery or Pharmacy. They must attend, if practicable, at the meeting of the Medical Council, on Tuesday, 1st April, at 3·30 o'clock p.m. Applications and testimonials, to be sent to the Secretary, on or before March 31st. Applications are also invited, in the event of an Assistant Surgeon being elected, for an Assistant Surgeon.

DEATHS.

BROWN, ROBERT GIBSON, M.R.C.S., L.S.A., at 144, Brixton-road, on March 21st, aged 52.

DAVIS, JOHN HALL, M.D., F.R.C.P., at 41, Boundary Road, St. John's Wood, on March 19.

HICKMAN, ARTHUR, M.D., L.R.C.S., L.R.C.P., Surgeon, Army Medical Department, at Jhansi, Central India, on February 19th, aged 30.

NICHOLSON, JOHN, M.D., formerly of Lincoln, at 40, Grove Road, St. John's Wood, on March 21st, in his 70th year.

TEEVAN, JOHN, M.R.C.S., of Woodside Court, near Croydon, at North End House, Croydon, on March 22nd, in his 83rd year.

THOMSON, ALLEN, M.D., D.C.L., LL.D., F.R.S., formerly Professor of Anatomy, in the University of Glasgow, on March 21st.

NOTES, QUERIES, AND REPLIES.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—I wish much to be informed if there is really any inconvenience in uniting in the same potion cherry laurel water and an alkaline bicarbonate. It appears to me that the hydrocyanic acid of the cherry laurel water has too weak affinities for it to be able to dislocate the carbonic acid of the bicarbonate, and form a cyanide of potassium or sodium. I ask the question, because, here, the physicians in general consider such admixture dangerous. I saw lately in a French work a caution against the conjoint administration of corrosive sublimate and cherry laurel water.

Has the electrical current been tried in London in *Lymph Scrotum*, or other manifestations of Elephantiasis Arabum, now proved to be dependent on *Filariæ?* Is Wucherer, of Bahia, recognised as the originator of this practice?

Not only was the alcoholic treatment of small-pox successfully practised in Scotland in the eighteenth century, as we learn from the pages of "Humphry Clinker," but measles were in Brazil treated popularly with rum and the dry excrement of the dog. This nauseous ingredient certainly owed its virtues to the presence of ammonia in some combination.

I have employed in uncomplicated asthma with surprising success the medicinal ($\frac{1}{10}$) solution of nitro-glycerine, in doses of one or one and a half drops every two or three hours in half an ounce of distilled water. When a hyperæmic state of the lung exists, I give tartar emetic for 24 hours previously to giving the nitro-glycerine. I lately had a case of Chorea Sancti Viti, in which the bromide of camphor (twelve grains per diem) cured the patient.

Is picrotoxin ($\frac{1}{10}$ of a grain, night and morning) employed in England against the night-sweats of the phthisical? I strongly recommend to practitioners in India, where the forms of fever seem to be identical with those of Brazil, the free use of the chlorhydrate of pereirina, extracted from the bark of the *Geissospermum Vellosii*, and to be obtained in the drug-stores of Rio de Janeiro. The dose may be from 12 to 24 grains in the 24 hours. It is intensely bitter, and is best taken in the wafer capsules, now in use for quinine and other nauseous or bitter drugs.

The efficacy of pereirina is extraordinary, and I have often seen it succeed after the failure of quinine. Its price is higher than that of sulphate of quinine.

Has *Hyoscyamine* come into general use in Europe? I find it of the greatest possible benefit in the nervous forms of typhoid fever.

I hope to receive authoritative information as to the query with which I commenced this incoherent communication.

RICHARD GUMBLETON DAUNT, M.D. Edin.

Campinas, San Paulo, Brazil.

APPOINTMENTS FOR THE WEEK.

March 29. *Saturday* (*this day*).

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

ROYAL INSTITUTION, 3 p.m.—Capt. Abney, "Photographic Action."

31. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

MEDICAL SOCIETY OF LONDON, 8.30 p.m.—Dr. Norman Chevers, C.I.E., will read a Paper on "Febris Exanthematosa Orientalis, otherwise Beriberi Fever."

April 1. *Tuesday.*

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 p.m.—The following Papers will be read:—Mr. Lane, "Spine from a Case of Spastic Contraction of Sterno-Mastoid" (card); Mr. Davies Colley, Juvenile Osteo-Malacia;" Mr. Sutton, "Bone Disease in Animals;" Dr. Norman Moore, "Ulceration of Small Intestine, and Disease of Skull, probably syhilitic;" Mr. Roger Williams, "Acne Keloid;" Dr. Hale White, "True Cystic Disease of Liver with Yellow Fever and Tuberculosis;" Dr. West, "Three Cases of Malignant Disease of the Bronchial Glands" (card), "Obstruction of one Coronary Artery;" Dr. Turner, "Cirrhosis of Liver," "Free Coagula in Pulmonary Vein" (card), "Extreme Obstruction of Coronary Artery" (card); Dr. Taylor, "Chondro Epitrochlearis Muscle on both sides" (living specimen).

ROYAL INSTITUTION, 3 p.m.—Prof. Gamgee, "Animal Heat."

2. *Wednesday.*

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

OBSTETRICAL SOCIETY, 8 p.m.—Specimens will be shown by Dr. Godson and others. The following Papers will be read:—Mr. Alban Doran, "The Relation of Prolapse of the Vagina to Hernia," illustrated by two pedigrees; Dr. Kilner, "Upon the Benefits derived from the Induced Current during Parturition;" Dr. Arthur Mitchell, "Strong Mental Emotion affecting Pregnant Women as a Cause of Idiocy in the Offspring."

ROYAL COLLEGE OF PHYSICIANS, 5 p.m.—Dr. James Andrew will deliver his Second Lumleian Lecture "On the Ætiology of Phthisis."

3. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

ROYAL INSTITUTION, 3 p.m.—Prof. Tyndall, "The Older Electricity."

4. *Friday.*

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL COLLEGE OF PHYSICIANS, 5 p.m.—Dr. James Andrew will deliver his Third Lumleian Lecture "On the Ætiology of Phthisis."

ROYAL INSTITUTION, 9 p.m.—Prof. J. G. Bonney, "The Building of the Alps."

CROONIAN LECTURES ON EVOLUTION AND DISSOLUTION OF THE NERVOUS SYSTEM.

Delivered at the Royal College of Physicians,

By J. HUGHLINGS JACKSON, M.D., F.R.C.P., F.R.S

Lecture II.—[Abstract.]

The hierarchy of nervous centres of the cerebral system, which was supposed to accord with the doctrine of evolution, was stated. The lowest motor centres are the anterior horns of the spinal cord, and also the homologous nuclei for motor cranial nerves higher up. The middle motor centres are the convolutions making up Ferrier's motor region. The highest motor centres are convolutions in front of the so-called motor region. It it needless to give the scheme of sensory centres. The main conclusions are: (1) that the highest (chiefly) sensory centres—parts behind Ferrier's sensory region—and also the highest (chiefly) motor centres—parts in front of the so-called motor regions—make up the physical basis of our highest consciousness; and (2) that just as consciousness represents, or is, the whole person psychical, so its anatomical basis (highest centres) represents the whole person physical—represents impressions and movements of all parts of the body.

The lecturer next endeavoured to illustrate the duplex symptomatology of certain cases of insanity—post-epileptic states. He wished to show that after epileptic fits, of different degrees of severity, there were different "depths" of dissolution, and, consequently, different "shallows" of evolution remaining; and at the same time to account for the increased excitability of the nervous arrangements on the different lower levels of evolution remaining.

It is well known that some epileptics, after their fits, are maniacal. The condition is called "epileptic mania," but it should be called "epileptic unconsciousness with mania." There is a negative, and there is a positive element. "Since the fit is over, and as the patient remains unconscious, there is, of necessity, on the physical side, loss of function of some of the highest arrangements of his highest centres—say, of the highest two layers. The co-existing mania is, I contend, the outcome of greatly raised activity of the next lower level of evolution remaining, the third layer, which is normal, except for hyper-physiological activity. But now comes the question, why is an unconscious man furiously active? Why, on the loss of function of the highest two layers, is the next, the third, layer in the state of hyper-physiological activity spoken of?"

In order to consider this question methodically, the prior epileptic paroxysm was considered. The conclusion come to, was that an epileptic paroxysm was owing to high instability of but a small part of the

highest centres—there was a physiological fulminate—by the rapidity of its discharge, it produced secondary discharges of healthy collateral nervous arrangements of the same general rank; thus there was a great multiplication of energy-liberations towards the periphery producing severe universal convulsion.

"The view I take is that the sudden and excessive discharge in an epileptic paroxysm produces exhaustion of nerve tracts, which had been travelled by excessive currents in that paroxysm. . . . . This is illustrated by a case of epileptiform convulsion of the left leg, followed by temporary paralysis of that limb. It will be agreed upon that in such a case there is disease of some part of the cortex in the right middle region of the brain (middle motor centres). And, since the event outside is excessive, it is obvious that the corresponding event inside is excessive. Further, in order that the central discharge, or 'explosion' inside, may 'get at' the muscles outside, the nerve currents developed must travel a particular route—passing down the internal capsule into the opposite lateral column of the cord, they will next overcome and discharge certain anterior horns (some lowest centres), and ultimately by peripheral nerves get at the muscles; there is excessive activity from cortex discharging to muscles convulsed. The explanation suggested (Todd and Alexander Robertson's hypothesis), of the temporary post-epileptiform paralysis, is that, after the excessive 'exercise' of central nerve-fibres during the epileptiform seizure, they remain for a time exhausted.

"Returning to the highest centres, we say that after an epileptic fit there is, according to its degree of severity, exhaustion of more or fewer 'layers' of those highest centres. As implied, I believe there to be also some exhaustion of middle centres, and of fibres in the lateral columns of the cord, and sometimes also of some of the lowest centres. (I neglect the implication of the lower centres.) Now, manifestly, considering the case of epileptic mania, exhaustion of part of the highest centres being a purely negative state, cannot account for the hyper-positive state, mania; the maniacal actions are supposed to be the outcome of the activity on the lower level of evolution remaining—of nervous arrangements which, except for hyper-physiological activity, are normal. Supposing the epileptic discharge to be strong enough to leave exhaustion of two layers of the highest centres—second depth of dissolution—then the maniacal actions would be the outcome of activity on the next (the third) layer of those centres. To show more particularly what is meant, we must speak of three degrees of exhaustion, three increasing depths of dissolution, which are affected by epileptic discharges of different degrees of severity, taking count of the three correspondingly decreasing levels of evolution. First depth.—There is defect of consciousness significant of dissolution of the topmost layer along with the rise of a certain kind of ideation significant of increased activity of the second layer. The double condition is roughly analogous to ordinary sleep with dreaming. Second depth.—There is loss of consciousness significant of dissolution of topmost and second layers, along with actions of more or less elaborateness (one example of which is post-epileptic unconsciousness with mania), significant of increased activity of the third layer. The double condition is analogous to sleep with somnambulism. Third depth.—There is coma, significant of dissolution of first, second, and third layers, with which, seemingly, there is persistence only of 'vital' operations, such as respiration and circulation, significant of retention of activity of the fourth layer. This double condition is analogous to deep slumber, to so-called dreamless sleep. It will be seen that the opinion expressed is that in each case the lower level of evolution remaining—the *then* highest level—is of some part of the highest centres. One thing to be especially borne in mind is, that in each of these degrees there is a negative, and that there is a positive, and often an hyper-positive element. Negatively, there are increasing degrees from defect, through loss of consciousness, to coma, signifying three increasing depths of dissolution; positively, there are decreasing degrees from elaborate ideation through actions to mere vital operations, signifying three increasingly shallow levels of evolution remaining.

After speaking of the first depth, the second was spoken of. "There has been a stronger discharge, which has effected deeper exhaustion—has exhausted, we are supposing, two layers. Now, there is no ideation, that is, none is remembered on recovery; but there are actions of different degrees of elaborateness from such highly special and complex actions as as those of a fisherman, when unconscious after an epileptic fit, pulling out a line from a reel, untying a knot, taking a hook out of his pocket, affixing it, and baiting it (doing all this pantomimically), down to such actions, if they deserve that name, as sprawling on the floor.

"The fisherman's case was a second depth of dissolution, in which we say, speaking loosely, that there was exhaustion of the highest two layers of the patient's highest centres, answering to his loss of consciousness. So much for the negative element. We recognise, too as the positive element, a lower level of evolution remaining, third layer, from activity of which he acted, as if he were on the river's bank. No explanation is adequate which does not account for the two diametrically opposite elements, not only for his ceasing to do this, but also for his beginning to do that. Putting it in another way, the patient's post-epileptic state differed from his previous normal state by a minus and also by a plus: there were two different persons, although in one skin; or, as the popular phrase is, the post-epileptic patient 'was not himself.' There was too little of him in one way, and too much of him in another way.

"The doctrine of evolution implies the passage from the most organised to the least organised, or, in other terms, from the most general to the most special. Roughly, we say that there is a gradual 'adding on' of the more and more special. But this 'adding on' is at the same time a 'keeping down.' The higher nervous arrangements evolved out of the lower keep down those lower, just as a government evolved out of a nation controls as well as directs that nation. If this be the process of evolution, then the reverse process of dissolution is not only 'a taking off' of the higher, but is at the very same time a 'letting go' of the lower. If the governing body of this country were destroyed suddenly, we should have two causes for lamentation:—(1) The loss of services of eminent men; and (2) the anarchy of the now uncontrolled people. The loss of the governing body answers to the dissolution in our patient (the exhaustion of the two highest layers of his highest centres); the anarchy answers to the no longer controlled activity of the next lower level of evolution (third layer).

"Another way of stating the general principle (which I call Anstie's principle), is that the over-activity of the lower level of evolution remaining *is not caused*, but *is permitted*; just as on cutting across the pneumogastric, the heart is not caused to go faster, but is permitted to go faster. In other words, the lower level of evolution is not 'goaded into activity,' but is 'let go.' So we see that exhaustion of the highest nervous arrangements—two layers—answers to negative affection of consciousness, and this exhaustion being at the same time a removal of control from the next lower level of evolution — third layer — it springs into activity.

"It comes to be a question of importance, and of more

practical importance than, at first glance, appears, whether or not in the second depth there is any mental state, in spite of the expression '*loss* of consciousness.' That there is activity of some nervous arrangements of the highest centres, we are supposing of the third layer, is, I submit, quite certain. The question is, do states of consciousness attend that activity or not?

"There will be two views on this matter. Let me return to the case of the fisherman, who pantomimically pulled out a line from the reel, &c., when unconscious after an epileptic attack. Had that man, who, on recovery, remembered nothing of his doings, any states of consciousness attending the nervous activity which produced his elaborate action? One view would be that the fact that the patient remembered nothing was proof that there were no mental states. Another view would be that the very elaborateness of the operation implied some co-existing states of consciousness, that, at the time, the man had ideas of the reel, line, hook, and of the bait. We must carry each view to its logical conclusion. Those who take the first view must say that the patient was a mere machine—a mere automaton. Otherwise stated, this opinion is that elaborate and universal movements may occur in a patient who has no trace of consciousness. On the second view it would be admitted that the man was a machine, an imperfect automaton, having lost the highest parts of his nervous machinery, but it would be said, too, that some degree of consciousness attended activities of the nervous arrangements on the lower level of evolution left. Each of these two views has consequences, as we shall soon see.

"We pass on to the third depth of dissolution. Supposing a severest discharge; when it is over the patient is comatose, lies motionless on his back, has seemingly no movements excepting 'vital' movements, such as the respiratory and circulatory.

"Having so far almost neglected the distinction between mental and physical states, we must now have special regard to it, the reason for which will soon appear. The current explanation of the post-epileptic comatose patient's immobility is that he does not move because he is unconcious. My belief is that there is paralysis. The objection which has been made to this statement is that, as a mere matter of fact, there is no paralysis.

"Everybody agrees that the post-epileptic comatose patient does not move *when* unconscious; I dispute that he does not move *because* he is unconscious. No man was ever unconscious without there being at the same time some physical change in at least the highest arrangements of his highest centres. I contend that it is more realistic to put his immobility down to this physical change—to attribute the physical to the physical—than to the correlative negative mental state. In other words, I give a realistic explanation in place of a metaphysical one. I put this question, 'If loss of consciousness were all, why should not the patient move as well as ever?' This question will not seem in the least degree strange to the majority of medical men, for they positively assert that an epileptic maniac who manifests universal and exceedingly elaborate movements has *no* consciousness.

"An objection may arise: it may be said, 'Your contention, that after a severest discharge the universal immobility is paralysis, is discrepant with your explanation of the second degree of post-epileptic unconsciousness and mania. If you say that exhaustion of three layers is causative of some universal paralysis in post-epileptic coma, you must admit that in the post-epileptic mania exhaustion of two layers also entails considerable paralysis. You are bound to say that the epileptic maniac has some universal paralysis, and that at the very same time he is in a state of universal activity.' My contention is, that there is some degree of paralysis all over the body, or, more precisely, loss of some movements of all parts, and that at the very same time there is persistence and over-development of some other movements of all parts, To show that this is not an extravagance, I would point out that local loss of movements of the whole of a part, with persistence of some other movements of the whole of that part, is an exceedingly common thing. Take the case of partial paralysis of an arm in hemiplegia. To say that the arm is 'weak' is misleading. The patient has lost some movements of the whole of the limb, and yet retains some other movements of the whole of the limb. Often enough there is loss of some of the most 'delicate' movements, with, at the same time, the retention of many 'coarser' movements.

"I contend that there is no difficulty whatever in conceiving, whatever difficulty there may be in believing, that the exhaustion of the highest layer, in the first depth, which defect of consciousness implies, is causative of a slight degree of paralysis 'spread out thin' all over the body ('weakness'); that exhaustion of two layers, which loss of consciousness, second depth, implies, is paralysis spread out more 'thickly' all over the body, notwithstanding that, from the raised activity of the third layer, other movements of all parts of the body, may be in great excess; and that the immobility in post-epileptic coma, third depth, is paralysis spread more thickly still.

"Since I say (1) that the highest centres are sensori-motor; (2) that negative affections of consciousness imply negative conditions of parts of the highest centres; and (3) that there is at least some defect of consciousness in every case of insanity, I ought to hold the opinion that, in every case of insanity, there is some degree, however slight, of universal or widely distributed paralysis—sensory, or motor, or both. So I do. That I could not demonstrate its existence in many cases, I admit. I should expect to find the least degree of negative affection of consciousness in cases of insanity where the accompanying positive condition was very elaborate—that is, on the physical side, when the dissolution was very shallow, and the level of evolution remaining was very high. In cases of dementia, I suppose the patient's "lethargy" would be put down to his negative mental state,—a metaphysical explanation. I should calll dementia the chronic analogue of what acutely is post-epileptic coma, and attribute the lethargy to the negative condition of more or less of his highest centres *implied by* his negative mental state, and call the lethargy paralysis. Paralysis is indirectly admitted in some cases in the assertion that there is loss of facial expression, difficulty of articulation, tremor of the limbs (indirect evidence of some paralysis), and shambling gait, when it may be denied directly. Taking but one of these symptoms, surely loss of expression implies either loss of the most special or 'delicate' facial movements, or continuous development of them (rigidity), or both. There is no abstraction 'expression' to be lost. What we know of any healthy person's conduct is from his movements. Such symptoms as I have enumerated are just those I should expect from negative lesions of the highest motor centres.

"Now for a serious qualification. This difficulty, taking the case of the fisherman, has to be met. There was so-called loss of consciousness, implying a deep dissolution, and yet the patient's very elaborate doings implied a very high level of evolution remaining. I hold that in post-epileptic states there are local dissolutions, meaning that the post-epileptic exhaustion is in, or preponderates in, one cerebral hemisphere. Thus, whilst there is a lower level of evolution in the highest centres of one half of the brain,

there is a perfect or very high level of those of the opposite half. Hence, the seeming discrepancy is explained."

The lecturer thought that cases of post-epileptic actions might be arranged in two broad divisions: (1) those in which the actions were relevant to some former surroundings, and (2) those in which they were relevant to present surroundings. This was a mere hypothesis. The comparative coherence of the conduct, so to call it, of post-epileptic maniacs had been strongly insisted on by Faloret, and this was, the lecturer supposed, explicable on the hypothesis that that they were local dissolutions. In many cases of uniform dissolution, the mentation was very incoherent; in many dreams there was a melange of the past and present (or very recent, rather). But both in cases of local and uniform dissolution there were "interfering conditions," which rendered their study exceedingly difficult. He then considered the several factors in cases of insanity, using the term insanity in the wide sense of departures from normal states of mind: (1) Different depths of both uniform and local dissolution of the highest centres; different depths of the latter he had just illustrated. (2) Different rates with which dissolution was effected, control removed; the more rapidly control was removed, the greater was, he thought, the activity on the lower level of evolution remaining. (3) Differences in the persons who had undergone dissolution, young or old, educated or uneducated, &c. (4) The influence of external circumstances, or local bodily states on the person, his lower level of evolution, who had undergone dissolution; commonplace examples were elaborate dreams developed by simple peripheral excitations.

RACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA, ESPECIALLY THOSE PREVALENT IN BENGAL.

By NORMAN CHEVERS, C.I.E., M.D.,
President of the Epidemiological Society of London.

(*Continued from page* 316.)

Febris Exanthematosa Orientalis, otherwise Beriberi Fever.[34]

I AM led by a careful enquiry into the ætiology of beriberi, and especially by a review of the history of the epidemic which visited Bengal and Mauritius in 1877 and 1878, to regard this malady as a specific fever, *sui generis;* and, consequently, to be of opinion that physicians will remove it from its present anomalous position in our nomenclature of disease, as the last and least defined in the roll of general diseases, and place it next to scarlatina, with which fever it has certain marked features in common.

We are told[35] that the word beriberi is derived from the Hindustani name of a sheep (*b'here*), from a fanciful notion that persons affected with the disease walk like a peculiar species of that animal, *i.e.*, with a kind of jerking motion; but the name by which it is known to the Gentoos of the coast, *Ooboo-waioo*, simply means rheumatism combined with dropsical swelling.[36] The writer adds, "This disease, though endemic in many situations, frequently also appears as an epidemic after the setting in of the rains, or from July to the close of the year, when fevers, dysenteric complaints and cholera also break out, to a greater or less extent annually.

Morehead justly objects to the unscientific vernacular designation of this malady; but the name beriberi has been so long accepted that it would now be useless to attempt to abandon it entirely, although our present knowledge of the ætiology of the disease renders it needful that we should modify it—as by calling it "beriberi fever."

The form of acute general anasarca, generally recognised under the name of beriberi, occurs as an endemic and as an epidemic. Its principal endemic habitats are Ceylon and portions of the Madras Presidency. According to Hamilton, the limits of the Indian *endemic* were the Malabar coast and that tract of country which extends from Madras to Ganjam, being confined to these parts, and extending no farther inland than forty miles. Later observation has considerably extended this endemic area, the limits of which it may have transgressed in recent times. Its ascertained *epidemic* range is exceedingly wide; its field occupying a very large expanse of the globe's surface—the South Pacific Ocean and its islands; the southern part of Australia and Mauritius in the southern hemisphere, and, in the northern hemisphere, as high as the Kasia hills, above the parallel of 25°. If we are to regard the epidemic which invaded Lower Bengal, in 1877, as true beriberi, as I think we must, the influence of this malady, when it becomes epidemic, may be expected to extend, in a plain country, as far as the sea breeze does, *i.e.*, about 250 miles inland—Calcutta standing 110 miles, and Shillong some 140 miles from the sea. Both places suffered in the recent epidemic.

Beriberi is most common among natives, and it attacks half-castes. European soldiers have often suffered; their officers occasionally, but far less frequently. It spares neither age nor sex.

Hitherto the scientific definition of beriberi has always appeared to be one of the most obscure problems in ætiology. Probably feeling this, the College of Physicians have, in their nomenclature, placed beriberi next to general dropsy, but have refrained from giving it any definition. Although its manifestations are numerous and complex, I think that, on carefully studying its phenomena, we cannot fail to arrive at the conclusion that true acute beriberi is not, as some have thought, a group of diseases, but a malady quite distinct from all others—a fever of varying type, but characterised by a very marked individuality. According to their opportunities of observing it, and to the type of disease with which each authority has been most familiar, authors have assigned various causes to this malady. Thus (1) Ranking held that it is renal anasarca; (2) Malcolmson viewed it mainly in its paraplegic and scorbutic aspects; (3) Morehead considered it to be an expression of scorbutic cachexia; while (4) others have regarded it as an outcome of paludal cachexia. Each of the leading authorities on the subject adduced very cogent facts in support of his opinion. I think, however, that an analysis of the characters of the epidemic disease which first appeared in Calcutta in 1877, and Mauritius in 1878, enables us to declare (5) that *acute beriberi is an exanthematous fever, hitherto best known by its sequelæ—acute general anasarca, and frequently but not invariably morbus Brightii and paraplegia.*

I shall review these five doctrines *seriatim*, save that I shall give precedence to the consideration of the fifth.

Fifth.—Acute Beriberi an Exanthematous Fever characterised by general dropsy, effusions into the serous sacs, and other grave sequelæ.

I have mentioned above that, in 1877, a disease having all the characters of acute beriberi made its appearance in Calcutta, and became rather extensively

[34] Read before the Medical Society of London, March 31st, 1884.
[35] "Madras Topographical Reports," Russel Condah, p. 89.
[36] Those who may be desirous to trace out fully the etymology of beriberi will find ample data in Fayrer's article, "Quain's Dict.," p. 104, and in vol. ii., O. S. of the *India Journal of Medical Science*, p. 343.

prevalent. No European is proved to have been affected. Eurasians and Armenians suffered. A very full account of this outbreak will be found in the *Indian Medical Gazette, passim*, for 1880, as contributed by various good observers, who were not at all unanimous regarding the nature and origin of the malady. None but those practically well acquainted with beriberi in its homes can judge with absolute certainty, whether we ought to agree with one or other of the only two Calcutta men who had seen beriberi. Dr. Coates, who had observed what was called beriberi in the Madras regiment at Cuttack, and who holds that the new Calcutta disease is not identical with beriberi, and Baboo Rammay Roy, who had recently treated some 500 cases of veritable beriberi in the Madras district of Coimbatore, and had, since his return, seen some 150 cases of the new disease in and around Calcutta, who asserted that "they were identically the same malady." My own conviction, arrived at after a very full survey of the whole question, clearly is that the Calcutta disease was true acute beriberi.

In early accounts of beriberi we frequently meet with such entries as these: "The disease commenced with fever, followed by swelling and numbness of the feet and legs;" "Had fever last night, skin dry, pulse excited." In the following quotation the italics are mine: "In detailing cases of beriberi, the cause supposed or probable should be first given, stating whether it was preceded by, or followed any epidemic visitation of disease in the district or neighbourhood, such as cholera, *fever* or dysentery; and also distinguishing particularly the *acute form of beriberi, attended with increased vascular excitement*, and coming on as a primary affection, from the chronic form which is frequently the sequela of rheumatism, *fevers*, &c." [37]

"Beriberi occurs both in an acute and chronic form; the acute form being usually attended by fever of an intermittent type, and of four or five days' duration, whereas the chronic form is more frequently the sequela of rheumatism or of fever, either of the intermittent or remittent form." [38]

In an abstract given by Malcolmson of nineteen cases of men, admitted with various diseases, who subsequently became the subjects of beriberi, five were admitted for "fever," and the eleven who were admitted for the four diseases—phlogosis, two; rheumatism, five; diarrhœa, one; anasarca, three—probably had commencing beriberi when they went into hospital. Malcolmson, and many who followed him, threw over this disease a darkness which has never yet been dispelled, by commencing their description of its symptoms at the beginning of the end. I cite Malcolmson's words (the italics are mine), "It (beriberi) usually *commences* gradually with a feeling of numbness, sense of weight and slight weakness and stiffness below the middle of the thighs." We might as well attempt to describe splenic cachexia by saying, "It usually *commences* with a pain and sense of weight in the left side." They fell into the great error of not enquiring strictly into the preceding fever. Doubtless their patients, not being properly questioned, did not enlighten them on this material point. Natives pay little attention to a single attack of fever, but usually seek relief when œdema and still graver symptoms occur. The severity of fever varies greatly in the exanthemata, and so does the amount and character of the exanthem, especially in the dark races. Judging by the light which the recent outbreaks in Bengal and Mauritius afford us, I am confident that Malcolmson, and others, erred in overlooking the fever and its exanthem, and by regarding the complications as the disease. In the epidemic which made its appearance in Calcutta in 1877, the initial fever and its exanthem were frequently overlooked, but it was generally noticed that the attack was ushered in by febrile symptoms of a few days' duration. It must be borne in mind that a malarious taint is to be suspected in the constitution of every Calcutta native; but it is clear that this fever was not the common paludal fever of Bengal. Many observers stated that there was no periodicity. Elsewhere, we read of evening exacerbations and morning remissions. In February, 1880, Dr. McLeod said that "fever sometimes preceded and sometimes succeeded the œdema, and sometimes did not occur at all. It seemed to be of quotidian type when present, and well-marked rigors ushered in the attacks."

Being a general practitioner, Dr. Chambers had an advantage over nearly all of those who observed the disease, in seeing cases from the commencement, while they, being consultants, were doubtless, in most instances, called in late. Indeed, Dr. Harvey remarked that, although he had seen many cases, he had not been able to have any one case under observation throughout. Dr. Chambers is the only reporter who says much of the cerebral conditions. He noticed marked head symptoms. He speaks of "intense frontal headache," and insomnia, and says that "when the disease is ushered in with great severity, there is a tendency to stupor and wandering delirium, generally confined to one particular subject. The patient is, however, rarely insensible, but is always roused up from the stupor and delirium by being loudly spoken to; sometimes furious delirium and violence occur."

Frequent mention is made in the reports to an exanthem. Thus, in a girl expressly stated to have escaped fever, Tumeez Khan says, "The limb swellings were stated to have been preceded by intolerable itching of the whole body, and the subsequent appearance of a rash all over it, and which, from the very vague description given, I think to have been of an urticarious kind." In 1879, Dr. Juggobuudhoo Bose had two cases in which "a redness of the skin, like scarlatina, preceded the swelling." In February, 1880, Dr. McLeod noticed, from large experience, that "the skin had been carefully examined, and in only one case was any abnormality found. This was a claret-coloured discolouration of the legs, disappearing on pressure." But he also stated, doubtless from the patients' own imperfect accounts of what had occurred to them, that the œdema "was preceded by burning and painful sensations, which seemed to be confined to the skin and soft parts." In a case of Dr. Nicholson's "there were purpuric spots." In March, 1880, Dr. Chambers, in describing the leading symptoms, mentions a "sensation of burning heat in the body, as though the skin were rubbed over with ground chillies, preceded or followed by repeated sensations of chill; a scarlet efflorescence from the beginning of the disease, especially confined to the face, neck, upper part of the thorax, and the extremities, or petechial spots with circumscribed measly eruptions on face or trunk, or large purpural or mulberry patches. In infants a marbly, mottled, purplish or red tinge of the skin, especially of the extremities, neck and cheeks; a flushed puffy countenance, with suffused glistening eyes." These observations become very noteworthy when we are told by Dr. Lovell that, in 1878-79, the Mauritius epidemic of "acute anæmic dropsy," as it was termed, was ushered in by "slight fever, and in most cases by a rubeolar skin eruption, disappearing under pressure, sometimes ending in petechiæ or phlyctænæ and desquamation." In Calcutta, the fever was succeeded by general anasarca. The œdema was by some described as being "hard and brawny." It usually commenced in the lower limbs, sometimes in the hands, spreading more or less to the trunk and head. "Œdema," said Dr. McLeod, "was doubtless the most constant

[37] Editorial remarks, *Madras Medical Journal*, p. 472, vol. i. for 1839

[38] "Madras Medical Topographical Report," Northern Division, p. 90.

LIVERPOOL ... INSTITUTION

symptom." "The œdema," said Dr. Harvey, "is general, not only throughout the connective tissue of the muscles, but the connective tissue of solid and visceral organs, in every cavity of the body, is bathed in fluid."

Dr. Harvey noticed that "in two cases there was an appearance of paralysis of the lower limbs, as if from effusion of serum into the spinal canal, and in a good many more there has been great difficulty in walking, apparently not due to paralysis, but to the local condition of the limbs."

Tumeez Khan's expression, that, in one of his cases, there was "inability of locomotion owing to excessive tension and stiffness of the lower extremities," appears to represent correctly the symptom in question in many cases. Dr. Chambers notices the occurrence of epistaxis in several instances. Capillary bronchitis was frequently present; pneumonic consolidation in some cases. Death commonly resulted from large, but apparently not inflammatory, effusions of clear serum into the pleuræ and pericardium. Consequently, there were palpitation and great præcordial distress and orthopnœa. Anæmic murmurs were frequently present. Dr. McLeod, speaking from large observation, stated that "death where it occurred would seem always to be sudden and associated with dyspnœa." Many early writers described the suddenness of death in beriberi. Malcolmson and McLeod use nearly the same words. The former wrote, "there is oppression and weight at præcordia, dyspnœa on slight exertion, diffused and irregular pulsation in the cardiac region." . . . . "The patient is often found dead in bed, or sinks after several fainting fits or throbbings of the heart." The urine was often noticed to be high-coloured, scanty (not always) almost suppressed, but there was no albuminuria or other evidence of Bright's disease. In a solitary case, which I think goes for nothing, there was "a small quantity of albumen." In some cases, the urine was of very low specific gravity. Here and there a case is reported to have commenced or terminated with diarrhœa, or there was diarrhœa at the height of the disease, or dysentery later on; but, in most cases, there was constipation; in several agonising pain in the lower bowel in defæcation. In many cases, in persons who were not sailors, the state of the gums gave evidence of scorbutus. In some the gums were healthy. In examining a considerable number of Bengalis, we may always expect to find that some are scorbutic, but it does not appear to be shown that scurvy was generally present among these patients. Still, Dr. McLeod observed that "in a few cases the gums were rather swollen and bled when the teeth were cleaned." "Neither an anæmic nor scorbutic condition appeared to be an essential precursor of the malady, though a certain degree of both dyscrasiæ seemed to be developed in its progress."

Most of those who observed the disease at its outbreak, in 1877, met with many cases which did well. In 1880, there were numerous deaths. In February, Dr. Cayley reported four deaths, and two persons in a dangerous condition in one family. In that month, Dr. McLeod, Health Officer of Calcutta, said that the town returns showed 266 cases and 51 deaths, and the suburban 364 cases and 163 deaths. It was observed by Dr. Harvey and others, that the disease was not confined to the poor and ill-fed; rich and well-to-do people, well-fed and living in well-raised and very dry houses, were quite as freely attacked as the poor, living in damp huts on the ground level. "The disease," says Dr. McLeod, "lasted for two or three months in well-developed cases." In the huge mass of evidence which I have analysed, I see no mention of the duration of very rapidly fatal cases, save in one, by Dr. Chambers, in which death appears to have occurred in three days.

There are only two reports of autopsies, made in February 1880, by Tumeez Khan. The most remarkable appearances were general œdema. Integuments of the lower limbs "hard and brawny," not pitting on pressure, and loaded with effused sero-sanguinolent fluid. There do not appear to have been any head symptoms during life, and no marked cerebral lesions were discovered. Large effusions of limpid serum, without traces of inflammation, in the pleural and pericardial sacs. Considerable œdema and carnification of the lungs. Heart flabby, normal in size (in one or both cases?), fatty. No peritonæal effusion, no noteworthy renal lesion. In both of Tumeez Khan's cases, as in most of the other reported autopsies, there was marked hepatic congestion. Blood thin and watery, with a marked excess of white corpuscles.

(*To be continued.*)

THE CHEMICAL EXAMINATION OF FOUR CASES OF ARSENICAL POISONING AT LIVERPOOL.

By J. CAMPBELL BROWN, D.Sc.,
Professor of Chemistry in University College, Liverpool; and
E. DAVIES, F.C.S., F.I.C.,
Analytical Chemist at the Royal Institution, Liverpool.

THE recent cases of arsenical poisoning in Liverpool have attracted so much attention, owing to the interesting legal questions decided during the trial, the wholesale character of the crime and the nature of the compound of arsenic employed, that it is perhaps desirable to place on record an authentic account of the chemical examination of four of the victims.

The first case examined was that of Thomas Higgins, who was first seen by Dr. Whitford, on September 25th, 1883, when he was found to be suffering from pain in the bowels and diarrhœa, and who died on October 2nd. The *post-mortem* examination was made on October 4th, and the stomach with its contents, the duodenum and the whole of the intestines, part of the spleen, the heart, one kidney, and a small part of the liver, were taken in a single jar (sealed) to Mr. Davies, at the Royal Institution Laboratory, Liverpool.

Judging from the redness of the stomach and intestines that the poison was probably arsenic, a microscopical examination was made, but no particles of arsenic, nor soot, nor indigo were discovered. Mr. Davies, on October 6th, extracted a considerable quantity of arsenic from 1 oz. of the contents of the stomach, and converted it into octahedral crystals of As_2O_3. He then chopped up fine an average mixture containing proportional quantities of the solid portions of the several viscera, and from 1 oz. of the mixture extracted a considerable quantity of arsenic which he identified by conversion into octahedral crystals of As_2O_3. Four ounces of this mixture were treated by Fresenius and Babo's method, and ·08 grains of As_2S_3 were obtained, equal to ·064 grains of As_2O_3.

Assuming the weight of the whole abdominal viscera to have been 80 oz., which is a very low figure, the weight of arsenic in the whole must have been, at least, 1·28 grains.

Part of the As_2S_3 was converted into arsenic acid, and precipitated with silver nitrate. The arseniate of silver was thus produced, and afforded confirmation of the identity of the arsenic.

Another 2 oz. of the mixed solid viscera was dried and distilled with strong hydrochloric acid; in one half of the distillate arsenic was detected by Marsh's test; in the other half arsenic was detected by Reinsch's test.

All the materials used in these investigations were first tested for arsenic, and found to be perfectly pure.

From these results, Mr. Davies gave it as his opinion that sufficient arsenic had been taken to cause death, because arsenic was undoubtedly distributed throughout the whole body, and much of it had been removed by vomiting and purging, as well as by excretion through the urine, and he believed it probable that the quantity remaining in the body after death was sufficient to kill a man.

On January 17th, 1884, the remaining portions of the viscera in the jar were taken to the Laboratory of University College, Liverpool, and on January 24th Dr. Campbell Brown commenced the examination. He extracted the arsenic from 2 oz. of the contents of stomach, and 2 oz. of the solid mixed viscera, and obtained, by Reinsch's method, a comparatively large quantity of crystals of As_2O_3, which he converted into the lemon-yellow arsenite of silver.

From $\frac{1}{2}$ oz., or 10 grammes, of the spleen separately, he obtained a comparatively large quantity of arsenic by Reinsch's method, and converted this into As_2O_3, and finally into arsenite of silver. He confirmed this by extracting the arsenic from the remainder of the spleen.

From $\frac{1}{2}$ oz. of the liver he extracted a small quantity of arsenic by Reinsch's method, and converted it into As_2O_3 and arsenite of silver. From a similar portion of the duodenum he extracted a considerable quantity of arsenic, and confirmed its presence in a similar way.

The proportion of arsenic in the spleen was at least five or six times as great (estimating it roughly) as in the liver, which contained very little arsenic, while the duodenum contained an intermediate proportion.

From these results, taken along with the other evidence, he inferred that a much larger quantity of arsenic must have been taken than was actually extracted, seeing that the arsenic pervaded the whole body, while some of it had been removed from the body by excretion, and by vomiting and purging; and he expressed the opinion that the deceased had died from arsenical poisoning, and that some of the arsenic had been taken several days before death, and probably some of it shortly before death.

Both chemists found arsenic in the fluff taken from a market pocket, found on one of the prisoners, and also extracted a considerable quantity from the pocket itself. In both cases the arsenic was converted into octahedral crystals and into arsenite of silver.

They both found a small quantity of a very dilute neutral solution of sodium arsenite, in a small flat spirit flask, taken from the dwelling of one of the prisoners. The sides of the flask were covered with brown coloured particles, and short particles of linen fibres.

Mr. Davies found in a portion of the stock of liquor bismuthi, from which the deceased's medicine had been taken by the dispenser of Dr. Whitford's prescription, bismuth, ammonia and citric acid, but no arsenic.

On the evening of the first day after the trial, Dr. Campbell Brown examined nine samples of different varieties of fly paper, purchased that day in Liverpool. In eight of these he found large quantities of arsenic in the form of neutral sodium arsenite, easily soluble in cold water. (The quantity was, after the trial, found to vary from 4 to $5\frac{1}{2}$ grains of arsenic per sheet.) The solution from each resembled the contents of the prisoner's, and in two of them the appearance of the colouring matter, as well as the fibres, corresponded exactly with the contents of the flask.

Some of these papers were labelled "poison," and some bore a printed warning to keep them out of the reach of children and animals.

The second case examined was that of Margaret Jennings, a girl of about twelve years of age, who died on January 25th, 1883, and whose body was exhumed on November 16th, 1883, having been in the grave about ten months. The *post-mortem* examination was made by Dr. Lowndes. Five jars were taken to Mr. Davies's laboratory, containing:—

1. The stomach and duodenum.
2. The liver, spleen and one kidney together.
3. The large intestines.
4. The small intestines.
5. The rectum, bladder, and uterus.

No. 2.—The liver, spleen, and one kidney, weighing only $16\frac{1}{2}$ oz., were examined first. In 1 oz. of the mixed contents of this jar, Mr. Davies extracted arsenic by Reinsch's method, and converted it into octahedral crystals of As_2O_3. He also treated $4\frac{1}{2}$ oz. by Fresenius and Babo's method, and obtained 0·3 grain of As_2S_3, which was finally converted into silver arseniate.

He next tested a portion of the spleen, liver, and kidney, each separately, by Reinsch's test, and obtained arsenic in the liver and kidney, but not in the small portion of the spleen taken; that is to say, the copper strip was darkened, but no distinct crystals of As_2O_3 were obtained.

No. 1.—In 1 oz. of the stomach he found arsenic by Reinsch's test more abundantly than in No. 2.

In Nos. 3 and 5 he obtained no distinct result.

From these results he came to the conclusion that the quantity of arsenic in the liver, spleen, and kidneys was about 1 grain, and that the arsenic in the whole abdominal viscera was not more than $\frac{1}{4}$ grain, and consequently he declined to say positively that arsenic was the cause of death.

On January 17th, 1884, the portions remaining in jars 1, 2, and 4 were taken to University College, and on January 23rd, Dr. Campbell Brown commenced the examination of them.

No. 1.—From the remainder of stomach and duodenum, about 3 oz., he extracted a small quantity of arsenic which was converted into octahedral crystals of As_2O_3, and finally into silver arsenite.

No. 2.—From portions of the liver, spleen, and kidney together, arsenic was extracted and identified in a similar way, and from about one-third of the entire spleen separately a small quantity of arsenic was extracted and identified in the same way.

No. 4.—From about 3 oz. of the small intestines a small quantity of arsenic was extracted and identified in a similar way.

No quantitative analysis was made.

From these results, he expressed the opinion that a larger quantity of arsenic than Mr. Davies found was actually present in the body, because it was distributed throughout the whole body, and part had probably been eliminated. He declined to say that arsenical poisoning was certainly the cause of death, although the presence of arsenic throughout the whole viscera afforded presumptive evidence of arsenical poisoning.

The third case was that of Mary Higgins, aged about ten years, who died on November 29th, 1882, was buried on December 1st, 1882, and whose body was exhumed on January 1st, 1884. The *post-mortem* examination was made by Drs. Whitford and Lowndes, who sealed up and delivered the following three jars, viz.:—

A.—Containing the stomach and contents.

B.—Containing the liver, kidney, and spleen.

C.—The large and small intestines.

On January 17th, Mr. Davies and Dr. Campbell Brown together made an examination of these. All the viscera were very much shrunk, but well preserved.

A.—The stomach was lined with a little dark grumous matter, but there were no measurable contents. In the folds were some crystals of ammonio-phosphate of magnesia, but no solid arsenic could be detected by the microscope.

C.—The vessels of the mesentery were remarkably yellow. There was nothing in the intestines, but the whole had a golden yellow colour, and there were many large crystals of ammonio-phosphate of magnesia. There was no solid arsenic.

From 1 to 1½ oz. of the contents of each jar were separately treated by Reinsch's test; arsenic was extracted from each, and was identified by conversion into octahedral crystals and lemon-yellow arsenite of silver. Arsenic was also extracted from one portion by Marsh's test.

The contents of *A* and *C* together weighed about 9 oz. One-half of both, or 4½ oz. in all, was treated by Fresenius and Babo's method, on January 22nd, and ·308 gr. of As_2S_3 was obtained, equal to ½ gr. of As_2O_3 in the whole of the stomach and intestines.

The identity of the arsenious sulphide was confirmed by chemical tests, and it was finally converted into arseniate of silver.

The contents of *B* weighed 16 oz.; one-fourth of this was treated by Fresenius and Babo's method, and ·154 gr. of As_2S_3 was obtained, equal to about ½ gr. of As_2O_3 in the whole of the liver, spleen, and kidneys. The identity of the arsenious sulphide was established in a similar way.

The quantity of arsenic found in the spleen and other organs, was sufficient to prove that a still larger quantity of arsenic had been taken, certainly enough to cause death.

The fourth case was that of John Flanagan, who died on December 7th, 1880, aged 22, and was buried on December 9th, 1880. The body was exhumed on January 16th, 1884, having been more than three years in the grave. The *post-mortem* examination was made by Drs. Lowndes and Whitford, who sealed up and delivered the three following jars:—

D.—Containing the stomach with part of the œsophagus.

E.—Containing the liver, spleen, and kidneys.

F.—Containing the large and small intestines.

The viscera were very much shrunk, but well preserved, and emitted very little odour. The stomach and intestines contained large crystals of ammonio-phosphate of magnesia, and nearly the whole of the intestines and mesenteric vessels were lined with a bright yellow coloured mud, especially at parts which were red and congested. No solid arsenic or arsenical compound was found by the microscope.

From 1 oz. to 2 oz. of the contents of each jar were treated separately by Reinsch's method, and a large quantity of arsenic was extracted in each case, this was identified by conversion into octahedral crystals of As_2O_3, and finally into arsenite of silver

Arsenic was also extracted by Marsh's test.

The contents of *D* and *F* together, weighed about 21 oz. On January 24th, one-sixth of both were treated together by Fresenius and Babo's method, and 1·672 grains of As_2S_3 were obtained, this is equal to 1·34 grains of As_2O_3 in the whole of the stomach and intestines. The arsenic was finally converted into arseniate of silver.

The contents of *E* weighed about 24 oz. One-sixth was treated by Fresenius and Babo's method, and 2·4 grains of As_2S_3 were extracted, equal to 1·92 grains of As_2O_3 in the whole of the liver, spleen, and kidneys. The identity of the As_2S_3 was established by chemical tests, and it was finally converted into arseniate of silver. From these results they stated their opinion that sufficient arsenic remained in the viscera to cause death, and that much larger doses must have been taken.

In cross-examination and re-examination, Dr. Campbell Brown denied that solid arsenic, or indigo, or soot would necessarily have been found if they had been taken shortly before death, but said that the failure to find these pointed to the conclusion that arsenic was probably taken in solution. He also denied the possibility of arsenic having got into the viscera from the soil of the cemetery, even if it had been present there. No arsenic was found in the grave clothes, and the coffin was intact when exhumed.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

METROPOLITAN FREE HOSPITAL.

A CASE OF FRACTURED RIBS—WOUND OF THE LUNG — PLEURITIC EFFUSION — ASPIRATION — PYO-PNEUMO-THORAX — FREE INCISION—RECOVERY.

By W. J. WALSHAM, F.R.C.S.,
Surgeon to the Hospital, &c.

[The following notes were taken by Mr. ENNIS, Junior House Surgeon.]

SAMUEL S., a boy aged 16, was admitted into the Metropolitan Free Hospital under the care of Mr. Walsham on the evening of November 3rd, 1882, having been run over by a hansom cab. On examination, the eighth, seventh, and probably the sixth ribs were found fractured on the right side, a little in front of their angles. As the patient was suffering from some amount of shock, and his respiration was considerably embarrassed, he was at once admitted and put to bed. The injured side was strapped, and a bandage applied. Three hours after admission he began to cough up bloody mucus, and subsequently almost pure blood. Crepitation was heard over the right base and at the seat of injury. He was put on low diet, an ice-bag was applied to the injured side, and he was ordered ice to suck, and to take Pil. Plumbi c Opio gr. iv. every four hours.

On the morning of the 4th, he appeared excessively distressed, respirations 60, pulse 120, small and thready, temperature normal; he was still coughing up large quantities of blood. In the evening, respirations 36, pulse 108, temperature normal.

On the 6th the hæmoptysis was less, but he still coughed up frothy blood and mucus. On the 12th, the hæmoptysis had quite ceased, and his chest, with the exception of some crepitant *râles* posteriorly, appeared normal.

At 9 a.m. on the 13th he had a distinct rigor, and at 12 noon the temperature had risen to 103° F. The hæmoptysis again returned, and severe pain in the side was complained of. He was ordered a linseed-meal poultice to the chest, and Quinæ Sulph. gr. 1 every four hours. At 9 p.m. the pulse was 140, respirations 60, temperature 102.

On the 14th his temperature was 103·8, pulse 140, respirations 66. Physical signs of fluid in the pleura began to appear, but the patient's condition was too serious for an accurate examination to be made.

On the 15th, the morning temperature was 100·3, pulse 160, respirations 72. The right chest was now completely dull to percussion. Breathing sounds were absent, except at the root of the lung over the whole of the right side; the heart's apex was displaced one inch to the outside of the left nipple line. Aspiration was performed, and three pints of bloody fluid were drawn off.

On the 17th, the right chest was dull to percussion as high as the seventh rib posteriorly; above this resonance was tympanitic, the breathing amphoric, and metallic tinkling could be elicited over the whole of the tympanitic region. Temperature 99, pulse 120. On the 21st, the chest was again aspirated, and about two pints of blood-stained fluid was drawn off.

On the 23rd, temperature went up to 102·4, respirations 42. Aspiration was repeated, and twelve ounces of purulent fluid were drawn off. The patient was now placed under chloroform, and the chest incised in Marshall's space under the spray, and dressed anti-

septically. A pint and a half of purulent fluid was evacuated. The fluid was mixed with air, and it was quite evident that there was a communication between the pleura and a large bronchus. After the evacuation of the fluid, the whole right side of the chest became tympanitic; the breathing sounds amphoric, and metallic tinkling could be elicited all over. The pleura was ordered to be washed out daily with carbolic lotion (1 to 100). Notwithstanding this, the discharge became fœtid; and it was found impossible to remove all the fluid through the existing opening. A counter-opening was accordingly made in the ninth intercostal space, nearly as far back as the angle of the rib. The washing-out was ordered to be continued. After the second opening was made, the discharge rapidly decreased in quantity and became sweet. The temperature fell to normal, the general condition improved, and the tympanitic note diminished. On December 4th the patient got up for the first time. On examination on the 6th the lung appeared to be expanding, and but little sputum was coughed up.

On the 20th, the opening in Marshall's space had healed. There was scarcely any discharge through the lower one. The chest was still washed out daily.

28th.—The patient was gaining flesh. The right side was much contracted, and there was a compensating spinal curvature with the concavity towards the right.

From this time he rapidly convalesced; the chest-walls fell in, and the lung expanded to meet them; the discharge from the lower opening rapidly diminished in quantity; he gained flesh and strength, and was discharged to a Jewish Convalescent Home.

On April 19th, he again came to the hospital. He was looking remarkably well, and had gained more than a stone in weight. The right side of the chest had markedly expanded; the percussion note, although slightly impaired all over the right side, was nowhere dull, and air appeared to enter the lungs freely. The lower wound had soundly healed. The lateral curvature had almost disappeared, and a cyrtometric tracing showed but slight difference in the two sides of the chest.

Remarks.—This case presents several features of considerable interest. Although it was not known, when the boy presented himself at the hospital, that the lung had been wounded, he appeared to have received a serious injury of some internal organ, and was at once admitted. The hæmoptysis did not come on till three hours after admission. When he was seen the next morning the bleeding was quite profuse, and his condition seemed critical. There did not appear to be any bleeding, or at least to any extent, into the pleural cavity, and there was no emphysema about the injured ribs. He had, apparently, quite recovered from the wound of the lung when he had the rigor ten days after admission, which seemed to be due to his taking cold in consequence of getting out of bed without leave in the early morning. The fluid, removed on aspiration, was of a dark red colour; it consisted of serum, mixed with a large quantity of blood. The communication between the lung and the pleural cavity would appear to have been produced by the yielding of the healed wound of the lung to the pressure exerted upon it on drawing off the fluid from the pleura with the aspirator. The aspiration was delayed for some time for the purpose of allowing the wound of the lung to consolidate, lest, as actually happened, in withdrawing the fluid from the chest, the communication between the bronchus and the pleural cavity should be re-established. The incision in Marshall's space failed to thoroughly drain the chest, and it was not till an opening had been made in the ninth space, far back, that this object was accomplished. The lad ultimately made an excellent recovery, and it would appear that his lung has received but little permanent injury.

Medical Times and Gazette.

SATURDAY, APRIL 5, 1884.

When on Monday last Lord Carlingford proposed that the third reading of the Government Medical Bill should be taken on Thursday, the Duke of Richmond professed himself incapable of comprehending why the Government should be in such a hurry to get the measure passed through the House. But everybody can understand, and to some extent sympathise in, Lord Carlingford's desire to have done with it. Having shown himself anxious to satisfy, or at least to pacify, all troublesome and dangerous opponents of the measure, he has met with the fate that usually attends such attempts; and so long as the Bill was before the Upper House, he was pressed to admit fresh amendments. When the Bill was in Committee, he proposed and carried an alteration in the Constitution of the Medical Board for Ireland, and we, last week, expressed a doubt whether the change would give satisfaction. On Monday, Lord Carlingford had to state that it had proved to be extremely unacceptable, and must be given up. On the third reading of the Bill, he accordingly proposed, that instead of allotting three representatives to each of the two Universities in Ireland, and a seventh representative to be elected by those bodies collectively, four representatives should be given to the University of Dublin, and four to the Royal Irish University. This change was accepted, and thus the Universities will have eight, and the Medical Corporations six representatives on the Board for Ireland. In the House of Commons, the Vice-President of the Committee of Council, Mr. Mundella, will have charge of the Bill.

The fervour and industry with which so many Members of the Lower House of Legislature have devoted themselves to the cult of "intelligent curiosity" are unbounded and irrestrainable; still, we would suggest to those among them who have taken under their special care the question of over-pressure in elementary schools that one of Mr. Mundella's latest answers on the subject may very well be accepted as sufficient for some time, though it is not in every point quite satisfactory. He states that the Education Department are convinced, by the overwhelming weight of evidence given by Her Majesty's Inspectors, that the alleged over-pressure does not exist, so far as the children and the requirements of the Code are concerned. They feel, however, that cases of over-pressure may occur under any Code that could be devised, and they have taken every possible precaution against this in the New Code. They are also confirmed in the opinion that the reduction of the hours of teaching by female pupil teachers was absolutely necessary, and they would be glad to give still further relief to them, if possible. Mr. Mundella added, that he had caused every complaint of over-pressure, alleged to be due to the Code, to be enquired into, and that in every instance the case had broken down.

THERE is not yet, however, any sign that Members of Parliament will cease, even for a while, to put questions on this subject. And in reply to another query of the kind Mr. Mundella said that the managers of public elementary schools will be generally held responsible for the conduct of the schools and of the school-masters, for issuing directions to the teachers not to press children of weakly constitution, and for seeing that such directions are obeyed. There are, he stated, two reasons for withholding children from examination—one for the protection of the child, and one for the purpose of obtaining larger grants for the schools. The latter must of course be discouraged, and the former encouraged, and the managers of the schools must be trusted, subject to the supervision and judgment of the Inspectors, to distinguish between the two classes of cases. This amount of control will probably not satisfy the critics of the elementary schools system; but multiple checks never work without considerable friction; and cannot be made absolutely perfect, as the final element must be, trust in some one human being.

THE revised Education Code, which has for some time been before Parliament, was discussed in both Houses on Tuesday night. The debate in the House of Lords ended in the withdrawal of an amendment proposed by Lord De la Warr. In the Lower House, Mr. S. Leighton proposed a resolution to effect three alterations in the Code, to secure:—firstly, "that scholars under seven years of age shall not be presented for examination individually, but by class"; secondly, "that greater liberty than at present shall be given to managers and teachers, to classify children according to acquirements and abilities"; and, thirdly, "that a larger share of the Government grant shall depend upon attendance, and a smaller upon individual examination." It was, however, clearly shown by Sir Lyon Playfair, who spoke forcibly in favour of the New Code, and by Mr. Mundella and Mr. Forster, that the first two objects of the resolution are met by the Code as it now stands; and that the third clause would not have the effect the mover desired, and might prove very mischievous to education; in the end the resolution was defeated by 184 votes against 135. Mr. Leighton stated, that the question really before the House was, whether over-pressure in schools should continue, or should be abolished, once and for ever. The latter object is not, we believe, for the reasons already stated, attainable. The many questions put on the subject, and the discussions provoked by them, have unquestionably done much good. They have drawn attention to the whole subject of over-pressure in schools, and to the necessity for constant and careful supervision of the working of the Code. But it will be well now to cease from public criticism for a while, and be content to watch the management of the elementary schools under the new and revised rules.

A CONSIDERABLE time has elapsed since any public statement was made as to the mischief done by the partial suspension of the Contagious Diseases Acts. But on Thursday last week Mr. Campbell Bannerman had to admit, in the House of Commons, the correctness of Lord E. Cecil's statement, that the rate of admission to Plymouth Hospital for contagious diseases had risen from 104 per 1,000 during the last six months of 1882, when the Acts were in full operation, to 230 per 1,000 during the last six months of 1883, when the compulsory examination provisions of the Acts were suspended. The figures quoted were taken from a return laid on the table of the House, on March 7th; and it is to be remembered that they refer to only a part of the evils that have followed on the action of Government in the matter.

AT the meeting of the Clinical Society, on Friday last, the proceedings opened with a paper by Dr. Finlay, on the association of enteric fever and rheumatism in the same person. The discussion on this subject did not add much to our knowledge, as most physicians have seen cases of enteric fever preceded by rheumatic symptoms, which have hitherto been regarded rather in the light of prodromata. One of Dr. Finlay's cases read as if the patient might have contracted the enteric fever in the hospital. There is no good reason why a person suffering from rheumatism should be proof against typhoid; indeed, there is evidence which points exactly the other way. Mr. Davies Colley's case of dislocation of the spine, treated by extension, is most encouraging, and ought to give a great impetus to so rational a mode of treating an injury, which too often, we fear, has been left untreated, because precedent, rather than common sense, has been allowed to rule the roast. Mr. Durham's case was one of those very obstinate so-called frontal neuralgias cured, after every less severe measure had been given a fair trial, by trephining. It would be interesting to know whether this operation often fails to bring about the much-desired relief.

THE Pathological Society on Tuesday last commenced their evening's work with the account by Mr. Davies Colley of a remarkable and closely studied case of so-called juvenile osteo-malacia. The child seems to have been under his observation during nearly the whole of her illness, and the case was therefore unusually complete. Mr. J. B. Sutton made a further communication on the subject of rickets in wild animals, summing up the result of his now considerable experience in this till quite recently almost undisturbed field of pathology. These two papers led Prof. Humphry, whose labours at the Medical Council had not deterred him from attending the meeting, to make some very interesting observations on the pathology of rickets, and on the changes that take place in the bones of old people.

AT this evening's (Friday's) meeting of the Glasgow Medico-Chirurgical Society Dr. Wolfe will show a case of total blindness from detachment of the retina, cured by operation.

THE sudden death of the Duke of Albany which has called forth such sincere expressions of sympathy with the Royal Family throughout the length and breadth of the land, is a misfortune for science in this country.

The late Prince had on many occasions evinced a deep interest in scientific questions, and as an active member of the Parkes Museum Council and the Kyrle Society, he had afforded proof that this interest was of a real and practical kind. As to the cause of his death we shall not here surmise, but we have it on the authority of no less a person than Sir William Jenner, that the Prince was the subject of hæmophilia. Now, it is well known to medical men that the life of a person suffering from this affection hangs by a thread, and there are several cases on record in which death followed very speedily on injuries which would have been but trivial to a healthy person. As to whether the death was due in this instance to effusion of blood on the brain or to epilepsy there is no evidence before us, from which we should be justified in forming an opinion.

The feeling which induced Dr. Chambers to introduce his motion at Wednesday's meeting of the General Council, in respect of the time-limit at *vivâ voce* examinations, and Mr. Teale to second it, will be appreciated and shared in by many, if not all, of those who have passed through the ordeal so well described by Dr. Chambers. The main object of an examination is to find out what a man knows; and in order to do this, surely the first thing is to set him at his ease. Now, the admirable machinery, as Mr. Teale called it, of the College of Surgeons Examinations is not, with the utmost deference to Mr. Marshall, in our opinion, well calculated to attain this object. We should very much like to know how many men really do themselves justice in that examination. Mr. Marshall says they never have any doubt about the decision in respect of any of their candidates—a truly remarkable confession; it cannot be in the best interest either of the examinees or of the public, that the verdict should always be an off-hand one. We would hope that Mr. Marshall has expressed himself too strongly, and that he and his colleagues do not really decide so hastily as he has led us to infer.

Sitting as both judge and jury, Baron Huddleston decided, on Tuesday, a case that may have very important consequences for medical officers of workhouses and lunatic asylums. A widow sued a Board of Guardians for compensation for the loss of her husband, who threw himself from a window of the workhouse infirmary to which he had been admitted in a fit of *delirium tremens*, and was killed by the fall. The widow gained her action, and was awarded 350*l*. by the learned judge. The main contention of the widow was, that the death of her husband was owing to negligence of the Guardians and of their servants; and negligence was unquestionably present and proved. A certain window had been reported as unsafe. In 1878, a patient in the same infirmary had committed suicide in precisely the same manner, by throwing himself from the same or a similar window. After that occurrence the Guardians placed bars to the window, but their medical officer had reported that the bars were insufficient and the window still unsafe. No alteration was made, however, and this was the negligence on the part of the Guardians that was relied upon by the plaintiff. The ward in which the deceased was placed was tenanted by forty patients, all of whom were under the care of a single nurse. This nurse was warned by the wife of her husband's suicidal propensities, but did not attach much importance to the warning, and during her temporary absence from the ward the act was committed. It was alleged that if the nurse had been present the act could have been prevented, and her absence from the ward was part of the negligence charged against the servants of the Guardians. The remainder of the negligence alleged was that of the medical officer, in sending the patient to the ward from which he threw himself, instead of to the lunatic ward; but it was proved that the lunatic ward, which held only three patients, was fully occupied at the time. The learned judge held that negligence was proved against the Guardians, against the medical officer, and against the nurse, found the damages as stated, and refused to stay execution pending an appeal.

It will be seen that this decision adds very materially to the responsibilities of Boards of Guardians, of visitors of lunatic asylums, and of the medial officers and nurses who serve these bodies. Looking at the matter from a narrowly professional point of view, it must first be said that medical superintendents have no cause to regret the precedent thus created. So long as they do their duty, and take every reasonable precaution, they have no reason to fear the consequences of an appeal to a jury. On the other hand, such a decision as that given by the learned Baron will immensely strengthen their hands in carrying out such alterations in the structure and management of asylums, and in the strength and efficiency of the nursing staff, as may be desirable for the safe custody of their patients. To the Board of Guardians the decision is very unsatisfactory, and it must be admitted is one of some hardship. Of course they ought to have guarded the window more securely; but then it must be borne in mind that a workhouse infirmary is not a lunatic asylum, and is not constructed, nor intended, for the detention and care of suicidal lunatics. The workhouse infirmary was not the proper place for this patient: he ought to have been in a lunatic asylum, and for the error in detaining him in the workhouse the Guardians are not directly responsible. Moreover, it is to be borne in mind that the man had brought himself to his condition of lunacy through his own act. He had drunk himself into a state of *delirium tremens*, and so became chargeable to the ratepayers; and now he has committed suicide through this voluntarily induced madness, the same ratepayers who supported him during his self-created illness are called upon to compensate his widow for his death. The inequitable character of this result will appear more conspicuous when we call to mind that about five years ago it was decided that the Guardians could recover the cost of his maintenance from a man who became chargeable to them in consequence of drunkenness.

Dr. Colton, of Portsmouth, on the Ohio river, writing to the *Medical Record*, March 15th, gives a graphic and sad description of the sufferings caused

there by the flood. For nine days his office and residence were under water, his medical books, the accumulations of thirty years, nearly all destroyed, and his medicines spoilt or washed away. He had to swim his horse to get to high ground. "I went," he says, "from house to house in hurriedly improvised boats, entering the second stories through the windows, or climbing ladders, passing over the roofs, and descending through hatches. There was much sickness and suffering, especially among children. Many women aborted from exposure and terror, and there were a number of cases of eclampsia among the parturient women. Many houses are wrecked, or have been washed away down the raging waters, with all their contents. Our people are impoverished, and it will be long before they have anything to 'spare for the doctors.' Six thousand of them are fed to-day by the generous gifts of the noble people throughout our land. If you know of any physicians in your city, who have duplicate copies of medical works, or anything in the line of physician's supplies, for which they have no use, they will confer a favour if they will send them to Portsmouth."

Any public institution in want of funds may mostly be left to take its own measures for raising money. The activity displayed by a lady connected with one of our hospitals is, however, causing a good deal of ill-feeling in certain aggrieved circles. Medical men, in a state of single blessedness, find it rather trying to receive a letter addressed to Mrs.——, enclosing a lithographed letter, to be passed on "to the children." The modest request for half-a-crown scarcely soothes away the feeling of irritation first excited. We have not yet heard whether similar letters were addressed to *all* members of the profession whose names are to be found in the "Medical Directory," but if so, we wonder how our sisters from the Ladies' School of Medicine appreciated this new phase of 'cuteness.

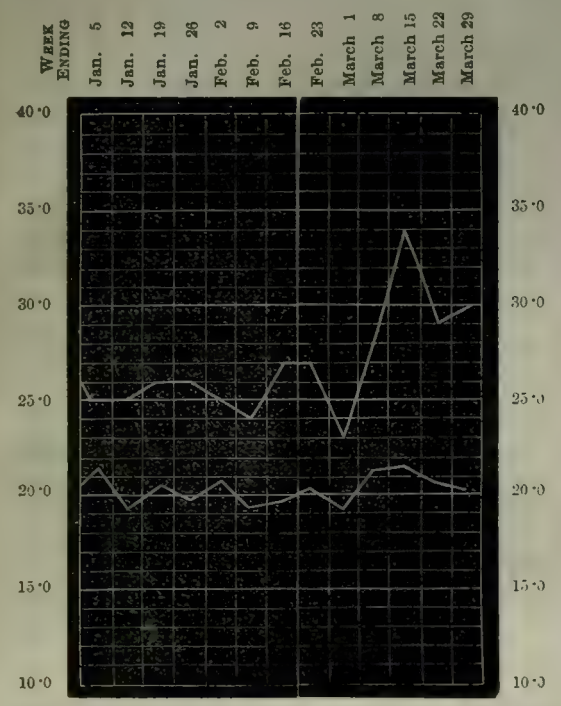
The truth of the old adage as to the superiority of Prevention over Cure has never better demonstrated itself than in the case of incurable epidemic disease. The value of its application to epidemic leprosy has of late been carefully investigated by Dr. Vandyke Carter, and the conclusions to which he has been led are to be found in a memorandum on the Prevention of Leprosy by Segregation, in the *Bombay Government Gazette* of March 6th, 1884. His paper chiefly consists of a critical examination of the facts and figures presented by the Director of the Leper Hospitals in Norway, where the gradual introduction of a system of segregation has been maintained for many years past; a further object of the paper being, to consider the possibility of introducing a similar system into India. In Norway, the results of segregation, whether in asylums or in the patients' own homes, have been decidedly satisfactory. The number of cases on record at the beginning of each year has diminished from 2,863 in 1856 to 1,717 in 1880; the death-rate also has fallen from 14·2 per cent. to 9·3 per cent. A few cases have been discharged as cured, but the permanency of this condition is probably open to question Still a large number of fresh cases are reported in each year; and it must often happen that before they can have been isolated, or even recognised, they have become *foci* for the local radiation of the disease in their respective districts. It has been, however, confidently prophesied, and the prophecy has been founded on figures, that it will be possible to eradicate the disease altogether, in the fulness of time, by strict adherence to this segregatory method.

The assertion sometimes made that leprosy is influenced in its origin by hygienic conditions is not borne out by the Norwegian experience. Improvements in hygiene offered no check to the progress of the disease until the establishment of the more radical system. The deterrent action, even of the latter method, has been very slow, although steady in mitigating the scourge, and it is still an undeniable fact that the *ratio* of the spread of leprosy in Norway remains unaltered. Applying the experience thus gained to the state of things in India, Dr. Carter is of opinion that isolation in some form or other is the only remedy which can reasonably be looked to as effective. The practical application of this view is possibly in three ways: I. By establishing properly supervised asylums. II. By founding leper colonies or villages. III. By isolating patients in their own homes. The main difficulty which would naturally arise in maintaining absolute isolation lies in the fact that so many lepers are in other respects able-bodied, and would be less likely to submit to any restriction of their liberty than are the sufferers from acute infectious diseases, who are willing to undergo the shorter term of isolation without question or complaint. Dr. Carter's paper is concluded by remarks on the bacillus of leprosy, and two excellent drawings are appended which show with great distinctness its resemblance to that of tubercle.

The death-rate of the 28 English towns last week showed a fall of 1·3, and that of the 8 Scottish towns a rise of 2·4 per 1,000 compared with the figures of the previous week. In the former, measles, scarlet fever, and diarrhœa were, comparatively, the most fatal of the zymotic diseases; in the latter, diphtheria and whooping-cough. The Scottish towns have an aggregate population of less than a seventh of that of the English towns, and yet diphtheria caused 18 deaths in the former to only 20 of the latter, 12 of which 20 occurred in London.

The most startling feature of last week's London return is the increase of small-pox. It has not told yet markedly on the death-rate, only eleven fatal cases being recorded; but the number of small-pox patients in the Metropolitan Asylums Hospitals and hospital-ships has almost doubled in the last fortnight, and on Saturday last amounted to 264. Ninety-two new cases were admitted during the week. Scarlet fever, diphtheria, and diarrhœa, on the other hand, appear to be declining, while the effect of the east wind of last week is shown in an increased mortality from whooping-cough. The

deaths from this cause numbered 112, or twelve above the average. We, again, append a chart, showing the



The lower line represents the annual death-rate per 1,000 from all causes in London, in each week of the last quarter.
The upper line represents the annual death-rate per 10,000 from zymotic diseases in London, in each week of the last quarter.

rise and fall of the general and zymotic death-rates of the metropolis during the past quarter.

From a paper recently read by Dr. Edward Otis, before one of the Boston societies, the practice of smoking by boys seems to be even more prevalent in the United States than among ourselves. As large a proportion as from 50 to 75 per cent. of the pupils in some of the large schools are said to indulge in the habit, their special instrument of indulgence being the cigarette. The authorities in the naval and military academies have, indeed, become so convinced of the prevalence and mischievousness of the practice, that they have prohibited it absolutely, and congratulate themselves on the good effects that have resulted from this action. Incorrigible smokers, we are told, have also been weeded out of other large schools. In one of these, on positive prohibition being contemplated, the principal issued a circular to the relations and guardians of the boys, in order to learn how far their co-operation and approval of the attempt could be relied upon. Of 160 replies, all expressed unqualified disapproval of the use of tobacco by boys, and 124 were in favour of absolute prohibition, the remainder not expressing an opinion on this point, or doubting its practicability. Dr. Otis confined his statement to boys, in whom he considered the practice is infinitely more injurious than in adults, and he sums up the results of the investigations he has made as to the effects of the cigarette smoking by them, as follows: 1. Impairment of the general development both physically and mentally. 2. The production of what has been called the "tobacco heart." Dr. Gibon, in his report on the U.S. Naval Academy, which led to the prohibition of smoking, has stated that at the annual examination of cadets, a large number of irritable hearts were discovered among boys who had no such trouble when they entered the school. 3. Defective muscular co-ordination, as shown in tremulousness in manipulation, and inability to draw a perfectly straight line. There is reason to believe that this is but a temporary condition, lasting only while the tobacco is used. 4. Reduction of intellectual power by impeding mental application and effort, or by deterioration of the intellect—probably by both, to a greater or less extent. 5. Impairment of memory, which would seem to be permanent. 6. Defect of vision, and more or less chronic irritation of the external parts of the eye. 7. Undue excitement of the sexual system, although the proof of this is not positive. 8. Irritation of the mucous membrane of the mouth and throat—especially in cigarette smoking. 9. Impairment of digestion and its consequences. The discussion which followed the reading of the paper did not throw any additional light on the topic treated on by Dr. Otis, the effect of tobacco on boys, the experience of the speakers being derived from their observations made on the adult in ordinary life. The importance of the subject was, however, duly estimated, and the absence of exaggeration in its treatment acknowledged

---

We are especially anxious to avoid the charge of being medical alarmists. A respected contemporary has been in the habit of crying "wolf" so often, that the lips of the laity are apt to curl, when they read medical warnings. Even a scientific grandmother may grow too garrulous. But we have formed such a strong opinion as to the deleteriousness of the growing and insidious habit of inhaling cigarette smoke, that we must risk the sneers of the youthful reader. The perils of the studio, and the risks of paddling—the danger of dabbling in "oils" and water, as someone described it—are problematical, and could only have been discovered by an effort of genius, but anyone can convince himself of the reality of the effect of inhaling cigarette smoke on the organism. Of ordinary cigarette smoking we say nothing; we do not believe that smoking a dozen cigarettes a day, in the ordinary way, ever did a grown-up person any tangible harm. But inhaling the smoke is a very different thing. Let even the most inveterate smoker try this experiment, and he will be convinced. Let him smoke an ordinary Turkish cigarette while walking, and at some distance from a meal, inhaling the smoke well into the bronchial tubes. Then if, before he has finished his cigarette, he does not find his head grow dizzy, or his heart begin to thump, or his fingers tingle, we shall be quite ready to congratulate him on the possession of an exceptional organism. Whether the effect is due to an impression on the terminations of the vagus, or whether the active principle of the tobacco is absorbed, and carried straight to the heart in the blood-current, we shall not undertake to decide; we only describe the fact. The effect may be transient, but we do not think that an effect so often repeated, as it is in the case of the confirmed inhaler, can fail to exert a permanent injury

on the economy. We have said nothing of the direct effect of the smoke on the bronchial epithelium, but we are convinced, from practical experience, that it may, in cases predisposed to it, give rise to a state of chronic catarrh. The habit, no doubt, is very enticing, the question is whether it is worth its risks.

Sir William Gull has promised to read two papers at the International Congress at Copenhagen; one on "The Pathology of Renal Diseases," and the other on "Collective Research," on behalf of the Collective Research Committee of the British Medical Association.

The *Louisville Medical Journal*, of March 15th, reports that its senior editor, Dr. Lunsford Yandell, who was well and favourably known to many of our readers, died suddenly on March 12th. It is a curious circumstance, that after the week's journal had been made up, Dr. Yandell ordered that it should not go to press until he had communicated a leader, for which space was to be reserved. This delay enabled the space so left to be utilised in announcing his sudden death.

Professor Zoldt, of Prague, has received the call to Vienna, as Professor of Anatomy, but he will not enter upon the duties of the office until the winter session. It is expected that his supervision of the erection of the new Anatomical Institute will be of great advantage. Professor Auspitz, has been elected as the successor of Professor von Zeissl, on his retirement from the post of Primar-Arzt in the department of syphilis at the Vienna General Hospital.

Dr. Orme Dudfield's report on the health of Kensington for the month of February last shows a death-rate for that portion of the metropolis of 16·1 per 1,000, which was as much as 4·1 per 1,000 below the decennial average. During the same period the deaths from the principal diseases of the zymotic class were 26, or 4 below the decennial average, allowing for increase of population; those from diseases of the respiratory organs numbered 57, including 41 from bronchitis, and 11 from pneumonia. It may be inferred, therefore, Dr. Dudfield's remarks, that the state of the public health continues to be satisfactory. One very satisfactory item which appears in this report must not be allowed to pass unmentioned, namely, that every death which occurred was duly certified.

Dr. Emmerich, Assistant of the Munich Hygienic Institute, discovered in some of the filling-in under the floor of a prison in Amberg an extraordinary quantity of the characteristic capsular micrococci, which have been described by Friedländer as the micro-organisms of pneumonia, and which, on subsequent examination, were found to be identical with them. This appeared to explain the occurrence of a great epidemic of pneumonia, which took place at Amberg, in 1860, in which no less than 46 deaths occurred in 161 cases. The fungi were found under the floor in the sleeping-wards in which these patients had lain. In the wards of the prison, which were free of pneumonia, none of these peculiar micrococci have been as yet found.

OUR COUNCIL.

The General Medical Council have met and dispersed, possibly for the last time under the existing *régime*, and the natural question which will arise to anyone who takes an interest in their proceedings is, what have they done? Our esteemed contemporary, Mr. Punch, is in the habit, in his Essence of Parliament, of summing up the work of each day in as brief terms as possible. We will not say, as he often has to say, that the Session has been absolutely barren, that the business done is none, but in truth it amounts to very little, and that little not done wisely or too well. Putting aside the usual number of black sheep, the consideration of whose cases occupied much valuable time in the earlier meetings, the Medical Acts Amendment Bill, now before Parliament, and the Scottish Corporations Conjoint Scheme, have been the subjects chiefly under discussion during the Session. The approval of the latter was carried, after a good deal of opposition, by a narrow majority, and the Scheme will, we are told, come into operation next October. Its supporters contend that they have thereby rolled five examining bodies into one. But is this really the case? It does not seem so to us. The various Corporations included in it will still have the power of granting licences to a candidate possessed already of a single qualification; and we fail to see that the number of licensing bodies is reduced at all. The approval of this scheme, at the present moment, seems to us, as was pointed out by many of the speakers, extremely unwise. If the Bill, now before the Legislature, becomes law, the scheme will never come into effect: for the licensing powers of the bodies who have entered it will be taken away. If the Bill does not pass, it will be the duty of the Council to take the matter seriously in hand, and not to rest satisfied with half measures, like those entailed by such a scheme as this. The promoters of the English Conjoint Scheme were well advised, we think, in not asking the Council, as they seem to have contemplated doing on Tuesday morning, to approve of their scheme.

In resolving themselves into a Committee to consider the details of a portion of the Medical Bill, the Council, if possible, acted in a still more unwise manner, and, indeed, they would seem to have repented of the error of their ways, for on Wednesday they refused to resolve themselves again into Committee to continue the consideration of the provisions of the Bill. Whether this was due to the fact that the Irish members, having got all they wanted, would not assist the Scotch members in their desire to air their grievances, we need not stop to enquire; the fact remains as we have stated. That the only point in the Bill which the Council debated, dealt with a money question, is, as Dr. Lyons justly observed, one that will not redound to their credit, or be likely to tell in their favour with Parliament, and it is well that they contented themselves with advising the Corporations what to do, instead of passing any formal resolution on so delicate a matter as a question of finance. We have been told that the Bill is one originating in the London medical journals, and that it is not desired by the general body of the profession. On this latter state-

ment we need only make two observations. It is true that the profession have not, as a whole, made any stir, or expressed any decided opinion about this Bill, and for a good reason; it does not, in so far at any rate as its main provisions are concerned, affect them in the slightest degree; it is a Bill introduced to protect the public, and to secure in their interests that no man's name shall be entered on the Register, without better guarantees that he is fully competent, than are at present provided. And, in the second place, the medical profession are not prone to take interest in any questions relating to medical education, as is evidenced by their absolute apathy with regard to the doings of the General Medical Council itself. The number of medical men, or indeed of men of any sort or condition, who have, of their own free will, attended to listen to the words of wisdom that have fallen from the lips of members of the Council during the Session just concluded, might be counted on the fingers of one hand. This is a sufficiently conclusive argument, that the lack of interest taken in medical education by the profession affords no ground for opposing the Bill. If the members of the profession had attended the meetings of the Council in any numbers, they would have been amply satisfied of the need for some such legislation as the present Bill proposes to afford. We are told repeatedly, that it behoves Englishmen to be long-suffering with the Irish, but we are sure that not even the most reasonable and patient man can spend an afternoon in the gallery of the Medical Council room, and not go away longing to wipe out the obstructive Corporations and their representatives with a wet sponge, and start afresh with a clean slate. That is, we admit, an unstatesmanlike frame of mind, and perhaps it is as well that so few members of the profession expose themselves to it.

HOSPITAL OUT-PATIENT REFORM.

I.—From the Public Point of View.

The difficult and complicated problem, how best to administer medical assistance to the sick poor, is a constantly recurring topic of discussion, and one which still awaits a satisfactory solution. The condition of the out-door patient departments of our great metropolitan hospitals more especially demands the attention of the reformer, and the consideration of this question has recently received a fresh impulse on account of the action of one of the largest charitable institutions in London: the authorities of Guy's Hospital having instituted a system of small payments by the patients to assist in defraying the cost of the medicine supplied to them. The results of this experiment, initiated for the first time, will be watched with considerable interest by all those concerned in the matter. Necessity, we are informed, has at last compelled the adoption of a procedure which has for long been urged, on principles of policy, and although at first sentimental objections will doubtless be raised, the movement thus started by so leading an institution has a fair chance of ultimately becoming universal. Further evidence of the attention this question of out-patient management amongst the public and profession is attracting, is furnished by the fact that, on Wednesday week, the first evening meeting of the Hospitals' Association was entirely devoted to its consideration, and the universal conclusion arrived at on this occasion was that reform was urgently required, although there was some difference of opinion as to the best manner in which this was to be effected.

By those who have studied the subject, it is with justice maintained that the present gigantic and costly system of wholesale gratuitous medical charity is a great social and moral evil, injurious alike to the poor, the profession, and the community. It serves to pauperise and humiliate respectable working men, to unnecessarily expend the time and energies of the doctor without satisfaction or profit, and to drain the pockets of the charitable and benevolent. The general public has a right to demand that assistance rendered to the lower classes be utilised in the most efficient manner, that no abuses in the system be permitted, and that the greatest possible good be effected at a minimum cost. These requirements are all the more necessary since, owing to the increasing population, to the ever-repeated claims for medical assistance, and the augmented cost of maintenance, the available funds are quite inadequate to meet the demands made upon them, and even the charitably disposed are now so importuned that a reaction must inevitably ensue to the disadvantage of suffering humanity. Hence has arisen the question as to whether the present recipients of hospital relief should not be called upon to participate in the support of the institutions founded in their interests, and by payments suited to their circumstances, in some measure to assist in defraying the outlay made on their behalf. This, as a social principle, is sound, as it is only reasonable that the well-to-do working classes should contribute towards the maintenance of their health, as well as towards the other necessities of life. The great difficulty to be faced is the reformation of old standing customs, and this problem has for long occupied, and still occupies, the ingenuity of hospital politicians, and much time and labour have been expended on its solution. The most important attempt in this direction was the formation of a committee in 1870, under the presidency of Sir W. Fergusson, which was composed of the most eminent and experienced physicians, surgeons and philanthropists in the country. They, after a most exhaustive and searching enquiry, published a report, which, for the general information obtained, and the value of the conclusions arrived at, will well repay careful study. Before and since there has been much literature on the subject, and more especially an admirable series of letters in the *British Medical Journal* (1877–78), in which the whole question is discussed in a complete and temperate manner. More recently the "Report on Hospital Management," edited by J. L. Clifford-Smith (1883), brings information on the entire subject up to the present time.

It may be admitted that the present system of indoor-patient administration works, upon the whole, in a satisfactory manner. The class of persons who enter a hospital are, as a rule, in comparatively indigent circumstances, due to their inability to work; and from the

serious nature of their complaints are deserving of charitable care and protection. With out-patients the case is very different, and on this subject the committee of 1870 came to the following conclusions :—(1) That the large majority of those who apply for relief at the metropolitan hospitals are the subjects of such trivial complaints as not to require any special skill in their treatment, and as such are, therefore, not suitable cases to occupy the time and attention of consulting physicians, but essentially come under the province of the general practitioner. (2) That the greater proportion of these individuals are in receipt of such wages as should enable them by small payments, according to their means, to accumulate in the aggregate such sums as would not only defray the expenses of their treatment, but would partly remunerate the medical man for work performed. The soundness of this double principle, namely, that, on the one hand, the theoretically special ability of the physician should not be employed in doing unskilled work, and, on the other, that well-to-do persons should contribute towards the allieviation of those minor maladies which do not influence the income of the bread winner, led the committee to propose the following resolutions :—Seeing that the actual pauper is already provided for by the State, all those who do not come under this category, yet who are unable to afford the ordinary scale of professional charges, should, by joining dispensaries on the provident system, provide themselves with paid medical attendance, which they would do at a minimum cost to themselves. It was further suggested, that these dispensaries should be affiliated with the hospitals, so that such cases as presented features of special interest, difficulty, or severity, might be drafted there, either to be attended to by the assistant staff, or to be admitted into the wards of the institution. Such a system, it was maintained, would augment the independence of the working classes, would remunerate the profession, would relieve the physician of unnecessary labour, and thus facilitate his powers of usefulness, would provide skilled consultations for the poor, and, finally, would be the means of devoting a large proportion of the funds derived from the charitable to other and more urgent purposes. These admirable propositions, although presented to the public some thirteen years ago, have, unfortunately, as yet been followed by no results of any importance. It is true, that certain provident dispensaries have been established, and many of these have proved successful even under the present adverse circumstances, but it is impossible that they can flourish on a large scale, when all the leading hospitals open their doors to any one who chooses to apply, and give to all out-patients of whatever kind and degree gratuitous advice and medicine. Hence, we believe that the movement initiated at the East End of London is a step in the right direction, and we trust that the example will soon be largely followed. It is scarcely to be hoped that the authorities of all existing institutions will unanimously overthrow all their cherished traditions and customs, and at once adopt a system of affiliation with outside provident dispensaries; at the same time the pressure for funds, and the abuses of the present system, must ultimately compel them to adopt some such measure. While waiting for this desirable consummation, the next best step is the formation of a dispensary at the hospital itself, after the manner already attempted at Guy's. If all patients were required to pay a few pence for their medicine, which we have satisfied ourselves would, with very few exceptions, be cheerfully complied with, a sum of money would be realised which would not only defray all the expenses of the out-door department, but would enable an honorarium to be given to casualty physicians, whose duty would be not only to attend to the applicants, but to select from them those who, from special circumstances, were suitable for the diagnosis, treatment, or teaching purposes of the hospital staff. Some such system, we are convinced, would be greatly to the advantage of all parties concerned. The patients with minor ailments would for a small payment obtain all that was requisite for their necessities, and those with serious disease would have gratuitous advice from the consulting physician, who, if necessary, would draft them into the wards. The casualty medical officer, if his work was unpalatable and mere routine, would at least in some measure be paid for his services; the physicians, on the other hand, would have the advantage of selected cases, with leisure for their observation and clinical demonstration. The general practitioner would in no way suffer, as by this means it is obvious that the competition with him would be diminished. The hospital would have money for other purposes, and the general subscribing public would have fewer demands made on its benevolence. With the possibility of effecting such improvements on the present unsatisfactory system of out-patient administration, it is to be hoped that the managers of our hospitals will, before long, see their way to take steps for its reformation.

REVIEWS AND NOTICES OF BOOKS.

MEDICAL WORTHIES AND OTHERS.[1]

The world knows nothing of its greatest doctors, and the profession itself knows about as much. The medical men whose names are most familiar in their lifetime, to all outside a very limited circle, are, with a few exceptions, not the men who are the greatest, but the men who are the most skilful in advertising themselves. Ask a country clergyman whom he considers to be the leaders of the medical profession, and he will mention names of men, whose only title to leadership is their own belief in their claim and fitness for that office. And if our best men are little known beyond their own circle in their lifetime, death, too, with us is robbed of its revenges. An artist, a poet, a writer, or lawyer dies, and however little he may have been prized in his life, the papers at once ring with his praises, the picture galleries are lined with his canvasses, his biography is in all the circulating libraries. No great soldier, or statesman, or civil servant passes

[1] "The Gold-headed Cane," edited by William Munk, M.D., F.S.A., London, Longmans, Green and Co., 1884.
"Memorials of John Flint South," collected by the Rev. C. L. Feltoe, M.A., London, John Murray, 1884.
"Gallerie berühmter Kliniker und hervorragender Aerzte unserer Zeit," von Dr. J. Hirschfeld. Zweite Auflage. Wien, Moritz Perles. 1880, 1882.

away, but some bookmaker is found to think the story of his life worth telling, and eager readers to think it worth reading. And yet we have had, and still have, in our midst men whose career and whose individuality are as worthy of the writer's and reader's attention as any of the great men who have graced other professions. But so far, few of them have found any biographer, and the general reader remains absolutely, and the professional reader relatively, ignorant of the work and character of the men who have raised, and are raising the practice of medicine out of superstitious empiricism into the region of reason and science. For the professional reader's want of curiosity in this matter there is some excuse. He is naturally and laudably more interested in things than in men, he attaches more importance to discoveries than to discoverers, and the whole character of his training and pursuits tends to dry up that love of personal gossip, which is the distinguishing feature of idle and inferior minds. But we do not quite understand why the general reader is so little interested in the life and work of our best men, and cannot but think that if they were put before him vividly and readably in a series of medical biographies, they would be read with interest by as large a circle, and would, perhaps, serve as high an educational purpose as the many lives of chancellors, authors, and statesmen, that are now so popular.

In the three publications which we have grouped together as the text of this article, an attempt is made in some small measure to supply this manifest desideratum. "The Gold-headed Cane" gives us highly interesting accounts of many London physicians long deceased. The "Memorials of Mr. South," besides conveying to us a picture—vivid and truthful, because drawn by himself—of one of the most lovable and high-minded men who ever bore sway in Lincoln's-Inn-Fields, gives us incidentally vignettes of most of the great surgeons of the earlier part of this century, drawn with a faithfulness and happiness of expression that remind one, except in the charity of their judgments, of Carlyle's more acrid sketches of his contemporaries. The "Gallerie berühmter Kliniker," on the other hand, taking us farther away in the matter of space, but less far in point of time, gives short biographies, with portraits, of the men who have made the fame of German medicine, and especially of the Vienna School. Since the early parts of the first edition of the "Gallerie" appeared, some ten years ago, more than one of the originals of its portraits have passed away, including the great names of Skoda and Rokitansky; but the majority are still continuing their active labours, and it is highly interesting to read by what steps and with what efforts they have climbed—often from a lowly starting point—to their present honourable position. The "Gallerie" has met with a considerable sale in Germany, and we doubt not that an enterprising publisher would find that a similar gallery of English medical worthies would attain an equal measure of success.

Returning to the volumes in which English worthies are depicted, we must, for literary excellence, give the precedence to Mr. Feltoe's book. As, however, it mainly consists of an autobiography, this credit is due to Mr. South himself. The autobiography deals only with the first twenty-six years of Mr. South's life, and ends abruptly with his appointment as demonstrator of anatomy at St. Thomas's Hospital. The remaining fifty-nine years of his life are told briefly, and rather baldly, by Mr. Feltoe, in little over twenty pages. The autobiography is charmingly written, and is readable from the first page to the last. Its interest for the thoughtful reader, however, will be chiefly in the picture which Mr. South unconsciously gives of his own character. He was evidently a man of a very highly strung organisation, both morally and physically, if the two mean not the same thing. Dr. Clifford Allbutt would have classed him as a typical neurotic, and would have found abundant support for so classing him in Mr. South's vivid description of a serious illness of his, marked by neurotic symptoms, which would now be properly interpreted, but which then appeared so serious to his attendant that they were promptly treated by repeated cuppings and blisterings, and a course of antimony and calomel. As a describer of others, Mr South appears to have been more remarkable for a keen power of observing externals, than for insight into what lay below. His pictures of his contemporaries, and notably of Astley Cooper, Henry Cline, and Abernethy, are terse and incisive, and seem to bring the very men before one, but he makes no attempts to pourtray their minds and characters. Probably, however, he gained in precision what he missed in depth, and, at any rate, it was this very precision which made his work as a surgeon, as a college official, and, lastly, as a writer of his own life, so admirable. Mr. Feltoe, we may add, has done his editor's work unexceptionably, and there are next to no blunders. By Sir Edward Home, on page 42, we presume Sir Everard is meant.

Dr. Munk's book is less satisfactory. Following Dr. Macmichael, who wrote the first five chapters, he has unfortunately adopted a worn-out and futile device, which is only workable in the hands of the literary expert. Unity may seem to be secured by making a gold-headed cane one's stalking horse, but unless the writer can reduce himself to the level of the cane, naturalness and congruity are sacrificed. This apart, the book is interesting enough; it gives accounts of nearly all the great physicians of the last and of the first fifty years of the present century, and though many of the anecdotes are amongst the stalest, the book, we think, will prove of interest both to the ordinary and to the medical reader. As in Mr. Feltoe's volume, we do not get any insight into the characters of the physicians described, and happily so, perhaps, in the case of some of them, for there are "unworthies," or "not worthies," as well as "worthies," described in both of these volumes. But medical biography, to be worthy of the name, must deal with its subjects philosophically, trying to gain a sympathetic insight into their minds, and showing wherein the value of their work consisted. Only on that understanding is it really worth doing. Neither of the present volumes, therefore, fills the gap we have complained of in the beginning of this article, but both will be found useful by, and will lighten the labours of, the future biographer of great doctors, if he ever

appears. We may add that Dr. Munk's volume is also carefully edited. If this were a society journal we should have to pull him up for writing Burleigh-on-the-Hill (p. 75), and inform him that Mr. Finch's "place," near Oakham, is spelt "Burley," and Lord Exeter's "place," near Stamford, "Burghley," but neither of them is ever now written "Burleigh."

Sound Bodies for our Boys and Girls; by WILLIAM BLAIKIE. With illustrations. London: Sampson Low, Marston & Co. — We heartily recommend this little book to our readers, they will find it useful not only for the instruction of their own children, but also for benefiting their patients, both children and adults. All medical men recognise the desirability of encouraging the physical development of the human body, but, as a rule, there are many difficulties in the way of carrying out ordinary plans of gymnastic exercise. To send children to a public gymnasium is generally expensive, and not always convenient. The same objections may be raised to the establishment of a private gymnasium, and consequently it is comparatively seldom that any steps are taken to ensure due exercise of the body. The book before us shows in the plainest and most practical manner how every part of the body may be efficiently exercised with the most simple apparatus; in fact, how almost every muscle may be worked without any apparatus at all. Moreover, the lessons are so arranged that the body is very gradually brought into working order, and if the instructions are carefully followed (and they are very lucid), no straining of any part of the body can occur. This little book ought to have a very large circulation.

How to arrest Infectious Diseases; by EDGAR BARNES, M.D. London: J. & A. Churchill.—The author, a medical officer of health, appears well qualified to deal with this subject; though apparently so simple, it is not always easy for a medical man to give terse instructions, when asked by his patients as to the steps which are necessary to stamp out infection or to prevent its spread. In the little work before us will be found plain directions on various points connected with infectious disease and its treatment; also something about disinfectants and how to use them. The language is simple, and the book on that account will be found very useful to the lay public, to whom we can cordially commend it.

Baldness and Greyness: their Ætiology, Pathology, and Treatment; by TOM ROBINSON, M.D. Henry Kimpton. Second Edition.—The work before us is a strange medley of anatomy, pathology, anecdotes, and extracts from classic and other authors. It indicates considerable research of a semi-antiquarian order, and its author has evidently bestowed some pains on its compilation. It is written, we are told, for "the student"; but, as "all pathological and descriptive details" have been curtailed, we fear it will not be of much use for scientific purposes.

The Teeth: their Formation, Diseases, and Treatment; by THOMAS GADDES, L.D.S. Eng. David Bogue.—This author candidly tells us that his "little work has been written for the public." It is on the same plan as, though it does not form part of, the series of "Health Primers," published by the same firm. It is freely illustrated, and contains much useful information concerning a set of organs, often too much neglected, on which our health and comfort nevertheless are largely dependent.

On Malpositions of the Kidney; by DAVID NEWMAN, M.B.—This is a thesis for the degree of M.D. of the University of Glasgow; it appears as a reprint, having been first published in the *Glasgow Medical Journal*. The author discusses his subject under three chief headings—simple misplacement without mobility, movable, and floating kidney. He adds an appendix of cases, and a full bibliography. The little work will be found a very useful and reliable summary of what is known concerning these subjects.

ABSTRACTS AND EXTRACTS.

A TYPICAL NEUROTIC.

In the life of the late Mr. South, which has been recently published by Mr. Murray, and which is reviewed in another column, there occurs (p. 135) a vivid description from Mr. South's pen of an illness with which he was seized in 1822, being then 25 years of age. He had been working very hard, he tells us, being every day six or seven hours in the dissecting-room, and in the evenings occupying himself with examining his pupils, or sitting up very late at night writing and drinking half a score cups of tea. In the midst of this work he was unexpectedly brought to a stand by illness.

"On the evening of March 21st, 1822, I had gone to bed rather earlier than usual, and had been asleep, I presume, about an hour, when I was aroused by seeing over me a gigantic hand and dagger held over my chest. Everything else in the room I saw distinctly, as it really was. . . . As might be supposed, I was horribly terrified, as I was lying on my back and utterly incapable of moving so as to escape the object of my alarm. At last, however, I managed to change my position, the spectre ceased, and, at the same time, I threw up a mouthful of the most acid fluid, which I can only compare to vitriol. I was very much agitated for some time. . . . . Next morning I was very ill; had a cobwebby sensation over the left side of my face, and a most curious feeling about the hinder upper part of the left parietal bone, as if my brain were being continually scratched with finger nails, in a space about as big as a crown piece. I do not recollect whether I had any headache, or what the state of my pulse was, but Dr. Cholmeley, who soon came to me, ordered me to be cupped on the scalp and blistered, and I think I was also cupped in the nape two or three times in the course of a few days and blistered, besides taking calomel and antimony, but not to produce ptyalism. In the course of the week the scratching sensation was relieved, but did not subside. I was soon after attacked with numbness, first of one leg and foot, and then of the other, so that I seemed at these times to be walking with my foot in a pillow. My hands would also become alternately numb in like manner, and in the space between the right thumb and fore-finger I had the sensation of a very hot iron resting on it, which sometimes was positively painful. Excepting the scratching in my brain, which continued for some weeks incessant and more or less severe, and the cobwebby feeling, which was not constant, but always restricted to the left side of my face, the numbness in my feet and hands alternated in a very strange manner. Sometimes my foot on one side alone was numb, sometimes the hand on the same side would be numb at the same time, or would be numb alone; at other times my right hand and my left foot would become numb, and then, again, the left hand and the right foot; and these sensations would last a day or two, but without any regularity. But the most persistent was the burning sensation, which was always confined to the right hand. These sensations, at very uncertain periods, continued with me for many years, and were always attendant on any digestive derangement. There was, however, only this exception, that the scratching subsided entirely after two or three years. The severity of this first attack began to diminish about three weeks or a month from its onset, and at the end of six weeks it was thought advisable I should go into the country, and the day was fixed, but on the previous evening, as I was quietly lying reading on the sofa, I was suddenly seized with violent palpitation of my heart, which being the first time I had felt it, terrified me so much, and was so distressing that I thought I was about to die immediately. The choking sensation and the violent irregularity of my heart, as if it were being wrung out of place, was most terrific, though I had often witnessed the same condition in my dear father, who for years had been subject to palpitation, always accompanied by severe and continued eructation for two, three, or more hours. After an

hour or two the severity of the attack subsided, but my pulse was very irregular, and for two or three days the least exertion, such as merely walking across the room, brought on the palpitation, and for some time I was obliged to lay hold of chairs or anything else at hand, as I had a terrible dread of falling to the ground. [After this Mr. South went to stay in the country, and his health slowly improved.] The palpitations did not cease, although they became less severe. But in reference to them was a circumstance which I could not explain. Whilst I was on horseback and trotting about, I had not any palpitation, and felt tolerably well, but directly I put my foot to the ground the palpitation recurred."

SURGERY.

Extirpation of Larynx.—A case of successful removal of the whole larynx for carcinoma is reported in the *Berliner Klininische Wochenschrift*, No. 5, 1884. The patient was a man of 72, with a good previous and family history. Having suffered from hoarseness for two years, he had become rapidly worse until the voice had been completely lost, the aphonia being quickly followed by dyspnœa and dysphagia. Pain in the ears and the back of the head was almost continuous. The lumen of the larynx was found to be almost completely obstructed by a tumour with an ulcerated surface. Immediate tracheotomy gave relief to the dyspnœa, and by means of a Michael's tampon, the inspiration of portions of the disintegrating tumour was prevented. Owing to the increasing difficulty of taking food by the œsophagus, the larynx was freely removed, a portion of œsophageal tissue attacked by the growth having to be taken with it. A hollow bougie was then fixed in the gullet, the trachea being still effectually guarded by the tampon. The wound was left open, but dressed antiseptically with sublimate gauze. The shock of the operation appears to have been trivial, the patient was allowed to get up in five days. Gradual advance from fluids to soft solid food was made without difficulty. The Michael's tampon gave pain on the fifth day, and was removed, its place being taken by a simple plug of sublimate gauze. The patient did well for four months, and then died from an attack of croupous pneumonia. The artificial larynx of Bruns, with Gussenbauer's voice canula, was worn with ease, and the patient was enabled to speak "loud and distinctly." It is to be regretted that no mention is made either of the microscopic character of the growth, or of any *post-mortem* examination of the whole body.

Management of Patients during Capital Operations.—In a paper read at the Boston Society for Medical Improvements (*Boston Medical Journal*, October 11th), Dr. Gay, of the Boston City Hospital, after narrating some cases, observed that it is generally believed that under the use of anæsthetics time is of little consequence in capital operations; but his own experience had taught him that the more quickly the operation is completed and the patient allowed to rally from the effect of the anæsthetic, the less will be the subsequent shock and exhaustion. This is especially noticeable in children, in whom a temporary collapse is not uncommon after a severe or a prolonged operation. There can be no doubt that a long operation is debilitating to the nervous system, even when it is done without pain and without the loss of much blood. Dr. Gay is also of opinion that while the primary effects of sulphuric ether are stimulating, the ultimate result is depressing, especially in persons prostrated by injury or disease. Another point he puts is that the pain experienced in the later stages of an operation is not detrimental, and that an opiate given before the operation tends to allay suffering and produces quiet; while the pain is less severe towards the close than at the commencement of an operation, as is seen during the imperfect anæsthesia which may have to be maintained in operations about the face. For these reasons, Dr. Gay removes the anæsthetic at a much earlier stage than is customary, and, as he believes, with beneficial result. He thinks that special attention should be paid to the following particulars while executing capital operations: 1. If shock or collapse be present, put nothing into the stomach, but stimulate by the skin and rectum. 2. Take pains to keep the patient warm by heaters, blankets, and a rubber sheet. 3. Disturb him as little as possible with examinations, moving, changing of clothes, dressings, &c. 4. Use the least possible quantity of the anæsthetic, and allow the patient to rally early, depending upon opiates to control subsequent pain and inquietude. 5. Finish the operation as quickly as compatible with its proper performance. 6. Get the patient into a warm bed as soon as possible, and without any exposure to cold. 7. Preserve the utmost quiet, and avoid doing too much for the patient until fair reaction has taken place.

A New Œsophagotome.—In the course of a paper on the "Value of Internal Œsophagotomy in the Treament of Cicatricial Stricture," published in the *New York Medical Journal*, Dr. H. B. Sands describes a new form of instrument which he has devised and used successfully. "The most difficult problem connected with the operation is that of exactly regulating the depth of the incision. I believe that this can be done only distending the stricture at the time when the knife is applied to it." The shank of the instrument is fifteen and a half inches long, and four millimetres in diameter, and consists of a flexible tube, made of narrow spiral steel plate—thus combining strength and flexibility—secured within by two pieces of fine wire, in order to prevent stretching or separation of the spiral coil. The instrument is provided with a number of steel bulbs, each bulb being furnished with a corresponding knife-blade. The bulb is screwed to the distal end of the shank, and the knife is attached to an inner flexible steel rod, manipulated by a thumb-screw at the proximal end of the instrument. By turning this screw the knife is drawn out from its concealed position within the bulb, the back of the blade sliding over a firm inclined plane. An index on a dial-plate indicates the amount of projection of the blade, the maximum projection being 2·5 millimetres. A small sliding ring on the spiral tube is used to indicate the distance of the stricture from the incisor teeth. The bulb being conical, the operator can readily perceive when it comes in contact with the stricture, before he projects the blade. In operating, a bulb must be employed which exactly fits the stricture; the depth of the incision will then just equal the distance to which the blade is projected by the action of the screw in the handle.

Extraction of a Leech from the Glottis.—M. Nepveu reported to the Paris Société de Chirurgie on the narration of a case forwarded by a military surgeon from Algeria. A robust Arab presented himself at the hospital, stating that for a fortnight past he had had a leech in his throat, which caused him to spit blood every ten minutes, and induced dysphagia, and a violent cough without much dyspnœa. On examination with the laryngoscope, the leech was observed to stretch from the summit of the arytænoid cartilage to the base of the epiglottis, leaving, however, the glottis pretty free. It was extracted living, by means of the Cusco forceps, and all the symptoms soon disappeared. M. Nepveu refers to six other cases which are on record, in two of which the patients died from suffocation before interference could take place. In one case Desault performed laryngotomy, and extracted the leech forty-six days after the symptoms had commenced. In another case laryngotomy was also required, while in two others the leech was removed by the forceps.

Skin-Grafting.—The material which is removed from the sides of a ruptured perinæum, when they are vivified preparatory to uniting them, makes the best skin-grafts to be obtained from any source. Being half skin and half mucous membrane, they are peculiarly adapted to the purpose; and a far larger proportion of the grafts will "take" when this material is used.—*New York Medical Journal*, January 19th.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 28TH, 1884.

Sir ANDREW CLARK, Bart., M.D., President, in the Chair.

Cases of Enteric Fever associated with Rheumatism.

DR. FINLAY read notes of five cases, the first of which may be taken as a type of the whole. The patient was a man, aged 24, a porter by occupation, admitted under his care into the Middlesex Hospital for acute rheumatism on October 1st, 1883. There was a strong family history of rheumatism, and the man himself had had one severe and several slight previous attacks. For a week before admission he had complained of pain, redness and swelling in the ankles, knees, and hips, the ankles being still affected on admission. His pulse was then 88; temperature 101·4°; tongue slightly coated, and there was a systolic murmur audible over the præcordium. The evening temperature on the day of admission was 103·4° Treatment consisted of salicylate of soda in 15-grain doses, with cotton-wool to the painful joints, under which he rapidly improved. His temperature became normal on October 5th, when he was also free from pain; and he appeared quite convalescent and was allowed to get up on the 13th. He continued to improve till the 19th, when he complained of stiffness in the back, and headache, and his evening temperature was found to be 102·6°. Next evening it was 104·2°, and from this time onwards the case presented the usual features of one of enteric fever. Rose-coloured spots were observed on the 25th and following days; diarrhœa set in on the 28th; and on the 29th perforation took place; and he died on the 31st. At the *post mortem* there was found general peritonitis, the result of a perforation through the lower part of the ileum. Two principal ulcers were found in the small intestine, one that had perforated, free from slough and with undermined edges; the other, with clean granulating base, to which the edges were adherent, clearly of more remote formation than the former. In order to establish the diagnosis of rheumatism, attention was drawn to the redness, swelling, and pain in the joints, the sour sweating, the endocardial murmur, and the history of previous attacks. As to the enteric fever, it appeared probable that it and the rheumatic attacks were co-existent on the man's admission to the hospital, the former being so slight as to be completely overshadowed by the rheumatic manifestations. The fatal attack was, therefore, a relapse; and this was attested by the different ages of the ulcers in the ileum, and by the course of the temperature. Of the four other cases, one, which was fatal, presented very similar features, the fatal result here being also due to perforation of the bowel, which occurred during a relapse. The remaining three presented no special features except the fact of enteric fever following upon an attack of rheumatism Notwithstanding the fact that no mention was made, even in recent writings, of the occasional association of these two diseases, such association did not seem to be very infrequent. In connection with this view, it was a point of some interest that of seven patients in whom enteric fever became developed in the wards of the Middlesex Hospital over a series of years, five were admitted for rheumatism. Such cases as those recorded suggested the enquiry whether there existed a more than casual connection between rheumatism and enteric fever—an attack of one predisposing to an attack of the other. As regarded the fatal cases, the question arose whether the allowing of solid food after the rheumatic attack passed off was in any degree responsible for the death by perforation. Two practical points seemed to be deducible from such cases: first, that as solid food might increase the danger of perforation in enteric fever, cases of rheumatism occurring in the course of an epidemic of enteric fever deserved a more than usually narrow scrutiny, lest they should turn out to be something more than rheumatism merely; and, second, that if any close connection between the two diseases, such as that hinted at, should be found to exist, rheumatic cases should not be placed in close proximity to cases of enteric fever. Although the facts were insufficient to prove a predisposition, they at least suggested a case for further enquiry.

The PRESIDENT asked whether Dr. Finlay's contention was that the diseases coincided, or whether they followed each other. He also asked Dr. Finlay whether he had considered the possibility that the rheumatic symptoms were only manifestations of the enteric fever.

Dr. FINLAY said that in his first case, the two diseases were certainly coincident, he did not think the second suggestion of the President's could be accepted.

Dr. DOUGLAS POWELL would have put the same question about the diseases being coincident. He had seen three cases which bore on the subject. The first was that of a lady, aged 40, who had previously suffered from rheumatism, and whom he saw on the fifteenth day of her illness, which had begun with rheumatic symptoms, on account of a supposed heart complication. The patient had many symptoms of typhoid fever, and on the twenty-first day some spots were seen, after a fall, for a few days, the temperature rose again, and the stools became typhoid-like. On the forty-second day there was hæmorrhage, and on the fifty-fourth day, a relapse of the rheumatic symptoms. The second case was that of a lady who, twelve days after being exposed to sewer gas, was seized with headache, and malaise; five days later, there was joint affection, and the next day pericarditis; five days after this, she had pneumonia, and slight albuminuria. Two days later, the abdomen was swollen, the motions were loose, and tinged with blood, and the symptoms were those of typhoid. Death occurred in six days, the diagnosis having been confirmed by Sir W. Jenner two days previously. The third patient was a woman, admitted into the Middlesex Hospital on the fourteenth day of her illness, which had been considered in the first instance to be rheumatism, but spots appeared, and the motions were loose, she was convalescent on the twenty-seventh day. In his cases the rheumatic and typhoid symptoms were blended, and there was no break between them, as was the case in Dr. Finlay's patients. In his first patient, the rheumatic symptoms had developed during the prodromal stage of typhoid. He did not think that such cases could have been overlooked if they had formerly existed.

Dr. DE HAVILLAND HALL had seen a similar case, where there was no interval between the symptoms of rheumatism and those of typhoid. A girl, twelve years old, had a sharp attack of rheumatism, with endocarditis, followed by a typical attack of typhoid fever. The rheumatism in these cases differed from that seen with scarlatina, in that it preceded, instead of following, the other malady.

Dr. POWELL alluded to a case where the rheumatism occurred at the end of a typhoid fever.

Dr. O'CONNOR thought the association of these two diseases was by no means rare.

Dr. SEYMOUR TAYLOR thought that the question was, whether the typhoid was a coincidence, or whether it attacked people who had had rheumatism previously.

The PRESIDENT said that such cases were not unknown to practitioners of large experience, and they were of much interest. The first question that suggested itself was what was the character and duration of the prodromal period of typhoid? In his own experience it often lasted as long as six weeks, and there might be diphtheritic, rheumatic, &c. symptoms, during it. Secondly, did rheumatism predispose to typhoid? Thirdly, were they diseases of close kinship?

And lastly, did the rheumatic symptoms sometimes precede and sometimes follow the typhoid? As to the point hinted at by Dr. Powell, he had no doubt that there were new diseases, as well as complications of old ones.

Dr. FINLAY, in reply, said that in his cases there had been a complete break between the two diseases, some being absolutely convalescent in the interval. In all but one of them the enteric fever followed the rheumatism.

Case of Dislocation backwards of the First Lumbar Vertebra which was successfully reduced under Ether.

Mr. N. DAVIES COLLEY read the account of this case.—A shipwright, aged 55, was stooping at his work when a mass of iron, weighing seven cwt., fell upon the small of his back. He was at once admitted into Guy's Hospital. He was collapsed, but quite sensible. The spine of the first lumbar was three-quarters to one inch behind that of the last dorsal vertebra. The adjacent spines were even, and formed a continuous series, those above at a level considerably anterior to those below. There was no movement nor crepitus to be detected upon gentle manipulation. He could move his legs, but the right somewhat less than the left. There was impairment of sensation on the outer side of the right leg, and complete loss upon the dorsum of the right foot. Soon after admission, extension was applied under ether. Mr. Davies Colley kept his hand upon the prominence, while three assistants made traction upon the legs. The projection was thus gradually reduced without any jerk; at the same time some crepitus and movement could be felt in the last dorsal spine. A plaster of Paris jacket, similar to the laminated form recommended by Mr. Furneaux Jordan, was applied in the horizontal position, while traction was still being made upon his legs. When he recovered consciousness he was quite comfortable. A more careful examination, two days later, showed that the right musculo-cutaneous nerve was completely paralysed, and there was some loss of sensation between the first and second toes, where they were supplied by the anterior tibial nerve. For ten days he was unable to micturate, and some small bed-sores formed over the sacrum, although, within two days of the accident he could turn over in bed and lie upon his side. On the thirty-fourth day after the accident the splint was removed. The line of the spine was then quite even. There was no deformity, and little, if any, tenderness. In less than two months after the accident he was able to walk, but he was still unable to evert his right foot. With the help of Faradisation he gradually recovered power and sensation, and when he was last seen, in October, no difference could be detected between the movements of the two legs, and the only abnormality in sensation was a slight numbness in the middle third of the outer side of the right leg.

Mr. BRYANT, after remarking on the great interest of the case just related, said that the practice therein recommended was not sufficiently recognised. He had seen three cases of supposed fracture of the spine in the practice of his colleagues benefited by extension, and had had two cases under his own care where the treatment had been adopted successfully. One of these was that of a man, aged 74, who was brought to the hospital an hour after a heavy sack had fallen on to the nape of his neck. There was paralysis from the nipple level downwards, no loss of sensation, slight priapism, and great pain in the right half of his body. There was projection of the third dorsal vertebra, with swelling around, and some separation of the spinous processes; there was also fracture of the sternum. Extension was applied, a sudden jerk was distinctly felt, and was audible to the bystanders; the deformity was completely relieved, and so was the pain which had been extreme. The next day some movement of the toes and of one foot was possible, but on the following day the anæsthesia had increased, and was complete the day after, and he died from respiratory troubles on the seventh day. The examination confirmed the diagnosis of dislocation of the third dorsal vertebra, which was found to have been completely reduced, there was some extravasation of blood into the spinal cord, but not enough to have produced permanent disorganisation, and had the patient been younger he might have made a complete recovery. He wished to advocate very strongly the treatment of such cases by extension.

Mr. HOWARD MARSH referred to a case of Mr. Willett's at St. Bartholomew's Hospital, wherein there was dislocation of one of the lower dorsal vertebræ, extension had brought about replacement, and after death the dislocation was proved to have been completely reduced, but he could give no details.

Mr. DURHAM had seen the case throughout, and congratulated Mr. Colley on the result. He did not now regard these cases as so hopeless as he was taught to in former days. He thought that there was some danger in the use of plaster of Paris jackets in these cases, except in the late stages, on account of the risk of producing sores which would be unrecognised and inaccessible.

Mr. DAVIES COLLEY agreed that the jacket would be objectionable, if with a fracture of a dorsal vertebra there was loss of sensation below the umbilicus.

Supra-orbital Neuralgia treated by Trephining.

Mr. DURHAM described this case. The patient was a horse-keeper who had always enjoyed good health, until knocked down by a horse and kicked on the forehead. The wound healed readily, and there was a sense of pricking in the scar afterwards. Some months later he was thrown out of a cart, and from that time had suffered from pain starting from the scar. He had never had syphilis. An immense number of drugs had been tried, but without avail. The pain was brought on very readily, almost any cause led to an exacerbation, the pain started internally to the scar which appeared healthy, it was doubtful if there was any swelling of the bone. He cut down upon and removed a portion of the supra-orbital nerve, stretching both the ends thoroughly, the pain returned one day later. In six weeks time he operated again, dissecting out and cutting away many of the branches of the nerve and pulling on their ends. The pain was not relieved, and the patient then fixed on a spot in the bone as the seat of the pain. A month later he was trephined at this spot, a piece of bone, an inch in diameter, being removed; there was no thickening of the bone. and no sign of past inflammation or suppuration or fracture; there was a little depression on the inner surface of the bone, but nothing had been noticed to have occupied this region during the operation. Since the operation there had been no recurrence of the pain, and his recovery was complete. It would have been more satisfactory if the cause of the pain had been recognised; he was inclined to class the case as belonging to "osteitis neuralgica," but in that affection the long bones were the ones that usually suffered, and they were almost always thickened or indurated, sometimes even eburnated. The little pit to which he had drawn attention was such as was commonly seen in adult skulls. He had no wish in bringing this case forward, to be understood to advocate this treatment in ordinary cases.

Mr. WALSHAM mentioned a case of Mr. Langton's, where a young woman, aged 22, had constant pain for two years after a compound fracture of the skull; she was trephined; some diseased bone being found, and made a complete recovery. In a paper in the St. Bartholomew's Reports he had collected 700 cases of trephining, of which thirty were for neuralgia, half of them attributed to a blow, the others having no causes assigned. In two-thirds there had been no return of pain after the operation; in only five had death occurred, and was not in them due to the trephining. In the majority the cause was disease of the bone, in ten no cause was found, in two a small granulation was

removed. In these cases we had to ask if the pain should be attributed to the injury, and if so where should the trephine be applied. He quoted two cases, one a young woman who had had a fall, and had a small swelling on the frontal bone, near the suture. Was the pain hysterical, or was it due to a possible exostosis on the inner plate? The other patient was an engine driver, who had an accident to the back of his head, and suffered from constant pain in the occiput. It was difficult to say where the trephine ought to be applied.

Living Specimens.

Dr. Willcocks.—A case of paralysis of the fourth and fifth (motor and sensory branches) cranial nerves, with a history of syphilis.

Dr. Seymour Taylor.—A man with dilated superficial veins over the front of his thorax, probably due to intra-thoracic aneurysm.

Mr. Bernard Roth.—A girl, aged sixteen, with lateral curvature illustrating the bad influence of dress on this condition.

Mr. Edmund Owen.—Artificial teeth swallowed, and passed *per anum* on the sixth day.

PATHOLOGICAL SOCIETY OF LONDON,

Tuesday, April 1st, 1884.

J. Whitaker Hulke, F.R.S., President, in the Chair.

Juvenile Osteo-malacia.

Mr. Davies Colley said the patient from whom the specimen was obtained, was a girl, aged thirteen, who had been under observation two years. She was the third out of four. The mother was a laundress, and the father having died some years previously; they were badly off, and lived in a cellar. She was healthy up to nine years of age, but walked with a waddling gait. She went away to school, suffered much from chilblains, then her knees began to bend in, and she broke her humerus. Later she broke one femur. On admission she was very tender about the tibiæ, they were very flexible, and could be dented on pressure. Later the lower jaw at both angles, and could be dented, there was a suspicion of fracture of the jaw. The bicuspid teeth became loose. The urine showed triple phosphates and pus corpuscles. On quantitative examination phosphoric acid was deficient, calcium in excess. Death from phosphatic calculi in kidneys and suppurative pyelitis. The head was much enlarged, upper extremities very much twisted, lower extremities less so. There was no pigeon breast, it was broad, barrel-shaped, the abdomen was considerably distended. At the *post-mortem*, excepting pyelitis, &c., the viscera were healthy. The bones showed two kinds of change, some were hypertrophied and dense, others brittle, rough, and light. The skull was dense, showed no diploe, and no appearance of outer and inner tables, at one or two points it was soft on outer side. Lower jaw thick, not quite so dense but very hard. Vertebræ were somewhat swollen and there was lateral curvature. The pelvis was very small, its left ala was much thickened and of gelatinous appearance, the other ala was exceedingly thin. The outlet of the pelvis was very small. The ribs were thin, a rounded swelling was present on the fourth rib on left side, it was a sort of callus formed on a fracture. Humerus much bent and twisted inwards, radius and ulna also very much bent and twisted. Femur bent, convexity outwards, and twisted on itself. Epiphysial line resembled that in rickets, it was thick and irregular. The long bones were thin in the shaft, rough and brittle, epiphyses were about the normal size. The disease closely resembled rickets in many points, but it also was very similar to cases of osteo-malacia. This case went to prove a close affinity between the two diseases. If forced to choose, he would think it was a case of osteo-malacia. 1. Because it occurred late in life. 2. Because of the calculi which formed in the kidney. 3. Thinness and flexibility of the long bones. 4. Utter useless of remedies for rickets. He had given her a course of cod-liver oil, iodide of potassium, iron and mercury, but they all failed to check the progress of the disease.

Mr. Symonds had examined the jaw, rib, ilium, femur, tibia, and skull; the femur and tibia showed a complete absence of compact tissue, the vessels were very large, the tissue was fibrous, periosteum was closely adherent. This wasting of the bone as it appeared to be, had led to the fractures. The swelling on the ilium was covered with a thin layer of bone. The jaw swelling and that on the rib were made up by concentric lamellæ separated by gelatinous tissue. The skull was porous, showing a very large space occupied by a fibrous medulla. In dried specimens the edge of the bone was in close contact with the medulla. The appearances were those of imperfect bone. Cornil and Ranvier had described very similar changes. The epiphysial line showed very great proliferation of cartilage cells.

The President said the points of this interesting case had been very tersely put. In several cases in adult women with osteo-malacia he had seen calculous disease.

Mr. Lane.—Rindfleisch said the first change was a decalcification. He supposed that as decalcification took place there was an attempt at the formation of new bone, but only partially successful. The fractures were merely very marked decalcifications and not really fractures. He had brought a larynx showing a condition bearing on this question.

Bone Disease in Wild Animals.

Mr. J. B. Sutton made a further and final communication to the Society on this subject. The question of age would, he hoped, be satisfactorily settled by his paper:—Rickets was, he said, a very common affection amongst carnivorous animals. Out of some thirty cases he had selected three groups of specimens to illustrate the question of age. 1. Specimens of rickets occurring in infancy, the young of the rare animal *Cynictis* had been chosen; they had died at the ages of three and four months respectively, and had beaded ribs, a deformed thorax, thickened bones, and enlarged epiphysial lines. Examination of a large number of skeletons had led him to conclude that the rickets of infancy attacked chiefly the appendicular skeleton, the thorax, and occasionally the skull; infractions of the ribs were common. 2. A nearly full-grown lion had never cut its teeth properly: for some months before its death it gradually became paraplegic. At the *post-mortem* examination the skull was found to be very thick, the ribs were beaded, the teeth were large but defective, the spinal cord was nipped by the enlargement of the epiphysial lines of the vertebral centra, and the encroachment on its canal of the intervertebral discs. The disease was equivalent to late rickets in the human subject, and its chief features were that the axial skeleton was most commonly attacked, but the spine and thorax only might be affected, or the vault of the cranium alone. Infractions of the ribs were common. 3. Much the rarest occurring in adult animals. The skeleton was much deformed, the bones were brittle, the teeth fell out, paraplegia was a prominent symptom; he would call this form the adult rickets of animals. There was one other form of the disease in young animals, of which he could offer no explanation, viz., where the bones were soft, the epiphyses large and rickety, and the diaphyses developed bulgings, the medullary cavities becoming filled with a diffluent oily material. He then detailed, at some

length, the views of M. Lataste, a Frenchman, whose observations strikingly coincided with his own. M. Lataste had been led to the following conclusions:—That rodents, in captivity, were exposed to a malady, the severity of which increased with the time they had been in the captive state. That under two distinct aspects, *rickets* in the young and *osteo-malacia* in the old, the disease consisted essentially in an alteration of the osseous system, either by absence of the assimilation or by reabsorption of the calcareous salts. Without wishing to fall into the error of drawing conclusions upon insufficient data, Mr. Sutton thought we were now in possession of the main features of this curious disease in three classes of animals:—Quadrumana, Carnivora, and Rodentia. One common group of causes—captivity and bad hygiene, gave rise to rickets of infancy and puberty, and a disease resembling osteo-malacia in the adult animals. The differences in the manifestations of the disease were due to the altered physiological condition of the skeleton incident to the three phases of life—infancy, puberty, and maturity.

Professor HUMPHEY said this was an interesting and difficult malady. In rickets we had an imperfection of growth or formation as shown in deficiency of size, for the bones were always small. There was not so much increased proliferation of cartilage as deficient calcification. If there was an increase, what became of it? He believed the increase was only apparent. Accordingly there were islets of unossified cartilage. Were the epiphyses enlarged? The epiphysial lines might be. The additions to rickets were two, absorption of material leading to thinning of the bone which might run on to mollities. The other was addition of bony material especially in the skull, a porous thickening, it might also occur about the lower end of the radius, the cause was unknown, not a direct rickety phenomenon. These two things also went on in old people, absorption of cancellous tissue of long bone, and the skull thick, hard, and heavy.

Chondro Epitrochlearis Muscle.

Dr. FREDERICK TAYLOR showed a patient who showed a web due to the presence of this muscle in each anterior axillary wall. It was the representative of a muscle in the anthropoid apes.

Mr. CLEMENT LUCAS mentioned the case of a child in whom he divided the muscle.

Mr. JOHN WOOD had never seen so well marked a case. On the two sides the muscles were not quite symmetrical. Sometimes there were slips from the ribs, and he had seen a double tendon. The muscle was very well developed in birds. He thought such a condition might be racial, it was not very uncommon.

Professor HUMPHEY said this was a variety of segmentation in the primitive arrangement. Low down in the animal series the pectoralis major and deltoid were not separated. They were the results of imperfect morphological development from lower types.

Intestines from a Case of Syphilis.

Dr. NORMAN MOORE showed a skull-cap and small intestine showing syphilitic lesions from a woman, aged 46, who died in St. Bartholomew's Hospital, in Dr. Gee's ward. The skull-cap was very adherent to the cranial fascia, and showed a node on its external surface. On the inner side of the right parietal bone was a bare patch, corresponding to which there was a dense local thickening of the dura mater, a partly degenerate gumma. The intestines were distended with fæces, though there was no single obstructed point. In the small intestine were numerous thickened patches, some ulcerated, some showing scar tissue and contraction, and some consisting of fresh connective tissue. The mesenteric glands were not enlarged. The liver was small, and showed many scars, and one recent gumma. The kidneys were small and granular, but without scars. There was a double pyosalpinx. There had clearly been long-continued obstruction at several points in the small intestine, for between the ulcerated places there was a slight general thickening of the intestinal wall. There was no amyloid disease. Visceral syphilis, though a rare cause of obstruction in the upper part of the large intestine, was of much rarer occurrence in the small intestine, and there was no similar specimen on record in the medical *post-mortem* books at St. Bartholomew's.

Keloid Tumour in the Neck.

Mr. ROGER WILLIAMS showed photographs of a female, aged 53, with a keloid extending across the neck, close to the hair. It was smooth, shiny reddish, surface showing follicular depressions with tufts of bristly hair. On pressure, semi-caseous matter exuded. The growth was of five years' standing. Microscopically, there was a new growth of dense fibrous tissue in the deep layers of the corium, with large vascular channels. The epidermis and papillary layer of the corium were nearly normal. The glandular structures had nearly disappeared. The disease was a variety of the keloid of Alibert.

Dr. O'CONNOR thought the name should be called cheloid.

True Cystic Degeneration of the Liver.

Dr. HALE WHITE brought forward this specimen. The liver was taken from the body of a soldier who died from yellow fever, and was found to be full of holes. Microscopically the condition was exactly the same as in cases already shown to the Society, *i.e.*, the presence of small vacuoles simultaneously in many hepatic cells, some running together to form large cavities visible to the naked eye. These contained the remnants of the broken-down hepatic cells. It was pointed out that this condition could be easily distinguished from fatty change, by its not staining with osmic acid, and also from *post-mortem* decomposition, which produced a spongy condition of the organ not containing air bubbles. The points of distinction between cysts due to vacuolation and those due to dilatation of the ducts were, that in the latter case, there would be a cause for the contraction of the ducts; and if the cysts were numerous, they would contain bile pigment, those that did not were usually congenital, large, and single. A liver full of cysts from cirrhosis was also shown. Under the microscope the difference was obvious. The cases brought forward by himself and Dr. Savage all occurred in lunatics, and all the organs were affected. The vacuolation could not be looked upon as congenital. Specimens were shown of that very rare affection in which tubercular deposit led to the formation of small cavities by breaking down; the cavities were small, and the disease only occurred in children. They could not be confounded with vacuolation.

Dr. NORMAN MOORE asked the time of the *post-mortem* after death. He was not convinced that these holes were not due to putrefaction. Pressure on the ducts did not produce cavities, it dilated the ducts enormously.

Mr. SUTTON said he had seen several cases in animals of vacuolated liver, the animals died from acute fever. It would have been more satisfactory if the patient had died from something else.

Dr. MAHOMED supported Dr. White's views. He did not think there could be any confusion between *post-mortem* vacuolation and this condition. The cases were rare, but certainly existed.

Dr. WHITE.—The examination was made from four to six hours after death. The points of difference between this and *post-mortem* change were very marked.

Card Specimens.

Dr. F. C. Turner.—1. Mitral stenosis from necrosis of valve. 2. Extreme obstruction of one coronary artery. 3. Free coagula in the pulmonary vein.

Dr. Goodhart (for Dr. Pye Smith).—Primary cancer of a cirrhotic liver.

Mr. Clement Lucas.—Kidney removed by nephrectomy.

Mr. Lane.—Spine from spastic contraction of sterno-mastoid.

HARVEIAN SOCIETY OF LONDON.

Thursday, March 20th, 1884.

Mr. George P. Field, President, in the Chair.

Spasm of the Muscles of the Face and Cataract due to Dental Irritation.

Mr. Henry Sewill's paper dealt with the case of a middle-aged lady, the subject of inveterate neuralgia, who, during late years, had suffered from a series of alveolar abscesses, and in 1881 had complained of recurring pains in the right eye, complicated, since January 1882, with persistent spasm of the right side of the face. In July, 1882, partial loss of sight from right cataract, and partial closure of the same eye from spasm of the orbicularis were superadded. In July, 1883, she consulted Dr. Ferrier, who, suspecting the symptoms to be due to dental disease, prevailed upon her to submit to extraction of the offending teeth. Mr. Sewill found in the upper jaw the stumps of some molars; and artificial bicuspids, incisors, and canines attached to a vulcanite plate, which had not been removed for years. The right canine was completely broken down, and pus exuded from several fistulous openings in the gums. The lower teeth were hidden beneath an enormous mass of tartar. The treatment consisted in extraction of all the upper teeth at two sittings, and in gradual removal of the tartar from the lower teeth. Within two days of the extraction the facial spasm entirely disappeared, but no change took place in the damaged lens. Mr. H. Power had lately stated, in a paper read before the Odontological Society, that dental lesions were very frequently the cause of diseases of the eye. Threatening glaucoma, especially when associated with ciliary neurosis and with obscure temporal and orbital pain; mydriasis, myosis, sudden paralysis of some of the orbital muscles and loss of sensation, in the absence of cerebral symptoms; phlyctenulæ and corneal ulcers, especially in children; sudden failure of accommodation and exophthalmos, were conditions calling for careful inspection of the teeth. To these should now be added cataract. Mr. Power had pointed out various ways in which irritation originating in the teeth might reach the eye: (1) inhibition; (2) trophic or vaso-motor influence; (3) extension of neuritis; reflex irritation or sympathy. The case recorded above was probably an instance of trophic disturbance.

The President called attention to the frequency with which the ear was affected from the same cause.

Mr. F. Treves referred to cases similar to that brought before the Society, which had occurred in the practice of Mr. Hilton and of Dr. George Johnson. Addressing himself to the anatomical aspect of the question, he criticised the theories suggested by the author for an explanation of the nervous mechanism at work. The case might lend support to the view that a nervous communication existed between the second division of the fifth nerve and the lenticular ganglion.

Mr. Juler considered Mr. Sewill's case to be one of great interest. He was of opinion that diseases of the teeth were very commonly the cause of ocular and intra-ocular lesions, and quoted some illustrative cases. In a young lady, aged seventeen, the right eye was very hypermetropic (6 D), and the vision bad, while the ophthalmoscope showed patches of recent choroiditis at the posterior pole of this eye. She was found to be suffering from a "retained" tooth in the left upper jaw, which was extracted, with considerable improvement in the vision. Another young lady had evident symptoms of inflammation of the ciliary region, and the vitreous was crowded with large membranous and fine floating opacities. She had carious teeth, and Mr. Juler had no doubt that the eye would improve if they were extracted. A third case was that of a delicate woman, aged 50, who suffered from persistent jactitation of the right eyelids. There was a carious tooth in the upper jaw of the same side; it was extracted, and with it disappeared all the facial trouble.

On certain Forms of Intestinal Obstruction that may follow after Hernia.

A paper on this subject was read by Mr. F. Treves.—Although after complete reduction of a strangulated hernia, and after recovery from the operation, as a rule, no further intestinal troubles may be expected, apart from such as depend upon fresh accidents to the rupture, certain forms of intestinal obstruction might follow after such reduction. (1) Stricture of the intestine due to cicatrisation after ulceration or sloughing of the mucous membrane, or to a form of contracting peritonitis. From the collected cases it would appear that neither the seat of the hernia, nor the duration of the strangulation, nor the nature of the operation, have certain or definite concerns in the production of these strictures. (2) Obstruction due to adhesions. The herniated loop may become adherent to the parietal peritonæum, and cause occlusion by "kinking," or the adhesions may lead to "bands" that may be the means of producing obstruction, omental bands are also common after certain herniæ. (3) Obstruction by the formation in the bowel of a rigid loop. Several examples of this form of obstruction were given, together with examples of a fistula bimucosa consequent upon injuries received by the strangulated bowel.

Mr. Gant took a different view from the author of the paper, with regard to the origin of stricture of the intestine and looped constriction, as forms of intestinal obstruction resulting from hernia. They were not subsequent conditions, but commenced from the time of operation, owing to the indentation often left upon the bowel at the seat of stricture, when the strangulated portions had been inadvertently returned into the abdomen in that condition. Hence the great importance of the rule he always observed, that of gently drawing down the gut, and of effacing the indentation by gentle manipulation before returning the part into the abdomen. The same might occur after the reduction of enterocele without operation, and it might be advisable to resort to operation to discover and release any such constriction, even when reduction could be effected by taxis, provided that the duration of the strangulation rendered it probable that plastic constriction might have supervened.

Mr. Cowell criticised the statement that the duration of the hernia had no definite influence upon the liability to subsequent obstructions. Some of the forms of obstruction, and especially those produced by bands of adhesion, were much more likely to be found in old herniæ. In many patients several different portions of intestine in succession found their way into the hernial sac, and were liable to be pressed on, each of them in turn becoming the seat of some inflammatory change and exudation.

The discussion was continued by Dr. Symes Thompson and Mr. Pepper. After which Mr. Treves replied, and the meeting was adjourned.

Paraldehyde and Strychnia.—In the course of a communication on paraldehyde, M. Dujardin-Beaumetz says that he has found in animals a remarkable antagonism between this drug and strychnia; animals thoroughly under the influence of paraldehyde may be given a dose of strychnia twenty times stronger than the maximum dose without producing fatal results. This antagonism is of extreme interest in conjunction with that between alcohol and strychnia. So far as has been ascertained at present, this antagonism is certain only as regards rabbits; cases of strychnia poisoning being too rare to have allowed the verification in the human subject—*Gazette Hebdomadaire de Médecin et de Chirurgie*, February 15th.

GENERAL MEDICAL COUNCIL.

FOURTH DAY—MARCH 28TH, 1884.

The Case of Mr. Matthew Bass Smith—The Case of Michael Healy—The English Conjoint Scheme—Preliminary Examinations—The Deficiency of Anatomical Subjects.

WHEN the Council adjourned on Thursday, the case of Mr. Matthew Bass Smith was still under consideration. Mr. Smith's name had been removed from the Register just ten years ago for an offence, the memory of which it would be ungenerous to revive, and it was now stated on his behalf, in a petition signed by a large number of medical practitioners and others, that ever since that date he had conducted himself as a gentleman of good moral character should do, and that he was now advanced in years and not in good health. The petitioners, therefore, appealed to the clemency of the Council, and begged that Mr. Smith's name should be restored to the Medical Register. Mr. Bass Smith, though not summoned before the Council, attended voluntarily on Thursday, accompanied by his solicitor and a medical friend, and gave the Council such explanations as were thought necessary. On the resumption of the discussion on Friday, Mr. Simon moved—"That a Committee be appointed to report to the Council on the facts in Mr. Matthew Bass Smith's case." This resolution, however, was not accepted, and in the end the Council agreed by nineteen against three to restore Mr. Smith's name to the Register.

Some technical business having been disposed of, letters from the Registrar of the Royal College of Physicians of London, and from the Secretary of the Royal College of Surgeons of England were read, intimating to the Council the withdrawal of those bodies from the Conjoint Scheme of 1877, which had never come into operation. The Rev. Dr. Haughton wanted to know why the scheme had never come into operation, and tried to get the Council to endorse his curiosity, but after a brief discussion the formal resolution he proposed on the subject was allowed to be withdrawn.

The Council next had before them the case of Michael Healy. This gentleman, a registered medical practitioner, had been repeatedly reported to them by that very active body the Liverpool Medical Defence Association, as guilty of infamous conduct in associating with a notorious quack called "Ethens Tomanzie," who had been sentenced to two months' imprisonment for fraudulent conduct in reference to the Births and Deaths Registration Act. Michael Healy had been warned to discontinue this flagitious connection, but paid no heed to this warning, and from a statement made to this Council appears to have died last Christmas *in flagrante delicto*. The Council discussed this case in private, but were unable to come to any decision, and adjourned its consideration to a more convenient opportunity.

Some remarks from Mr. MACNAMARA, on the relinquishment of the English Conjoint Scheme had the effect of calling up Dr. HUMPHRY, who said that having been more than anyone else associated with the growth of the Conjoint Scheme in question, he was possibly better than anyone acquainted with its aims and intentions. The scheme was devised and perfected by all the English bodies in conjunction, and they had fully intended to carry it out. If England was at fault, the fault lay at Scotland's door. It was felt unwise to carry it out in England, unless it was likely to be carried out in each of the other divisions. He thought it would have been wiser had England carried out the scheme, but she naturally hesitated to go on while Scotland held back, less there should be an increased emigration of English students to the easier examinations of Scotland

Prof. MARSHALL also contended that the action of the English bodies had been retarded by the delay of the Scotch division of the Kingdom in proceeding with a conjoint scheme. The appointment of the Royal Commission and impending legislation served further to create delay. If Government should fail in settling the question of reform, it would then remain for the Colleges to unite in forming a combination to carry out the scheme.

After remarks by the Rev. Dr. HAUGHTON, Mr. TEALE and Dr. SCOTT ORR, the PRESIDENT alluded to the high importance of this discussion. Fourteen years ago he endeavoured to promote a conjoint examination scheme. At more than 70 meetings, extending over four years, he advocated such a scheme. The Council had recognised the evil of many examining boards, and that a reduction of their number must either voluntarily or by law be made. He felt that the matter demanded action, and that the opinions of politicians and others should not influence the proceedings of the Corporations in this respect. The state of the existing political atmosphere was too uncertain to admit them to place reliance on legislative action in producing what they wished; and the difficulties under which students labour demanded that something should be done for their relief, and such a means was, he urged, to be found in a conjoint scheme of examination.

The rest of the sitting was almost entirely taken up by a discussion of the subject of preliminary examinations. Several communications in connection with this subject were before the Council. First, the Report of the Preliminary Examinations Committee, consisting of Sir Henry Pitman, Dr. Humphry, and Dr. Haldane. The Committee had been appointed by the Executive Committee to consider a letter from Mr. Rendle, the secretary of St. Thomas's Hospital Medical School, asking for information as to whether students who had not taken mechanics in their preliminary would be called on to pass it subsequently.

The Committee stated in their report that they "feel that in this and other respects the subject of preliminary examination requires the consideration of the Council, but the present period appears to the Committee to be most inappropriate for entering upon this consideration. Should the Bill now before Parliament become law during the present Session, the consideration of this subject would devolve upon another body. Should it not do so, it would be the duty of the Medical Council to lose no time in entering fully upon it."

The report having been received, it was moved by Mr. SIMON, seconded by the Rev. Dr. HAUGHTON, and agreed to—"That, in answer to Mr. Rendle's letter, the Registrar inform Mr. Rendle that the regulation to which he refers (that students who have not in their preliminary examination passed an examination in the elementary mechanics of solids and fluids shall pass this examination before or at their first professional examination) is a regulation to which the Council attaches much importance, and which it intends to be strictly observed."

The Council had next before them a communication from the Oxford and Cambridge Schools Examination Board, in which attention was drawn to the varying requirements of the lower certificate of the Oxford and Cambridge Board and the junior certificate of the Cambridge Local Examinations Syndicate, both of which are accepted by the Council as recognised preliminary examinations. The latter, however, does not require a knowledge of English history and geography, and accordingly the secretaries of the Oxford and Cambridge Board suggested that they should be allowed by the Council to omit those subjects from their requirements. It was now moved by Dr. HUMPHRY, and seconded by Mr. TEALE—"That the request of the Oxford and Cambridge Schools Examination Board, to be allowed to omit the words 'English history and geography' from the list or subjects required by the Medical Council for the recognition of its certificates, be acceded to." A long and amusing discussion took place, but as the hour of adjournment was approaching, the motion was in the end withdrawn.

The last business of the day was to receive the Report of the Committee on the Deficiency of Anatomical Subjects, which has been sitting for the last two years. The gist of this report was that the Committee was unanimously of opinion that it would be undesirable to seek for further legislation on the subject.

Fifth Day—March 29th.

The late Duke of Albany—The Cases of D. M. O'Hara and W. Story—The Conjoint Scheme of the Scottish Corporations.

After the minutes recording the labours of the previous day had been duly read and approved, Sir Henry Pitman rose to ask the President what steps he had taken to carry out the wishes of the Council in reference to the death of the Duke of Albany.

The President, in reply, read the following letter, which he had drafted for the approval of the Council.

"May it please your Majesty,

"We, the General Medical Council of Education and Registration of the United Kingdom, have learnt with extreme sorrow this day, during our ordinary sitting, the blow which it has pleased God to inflict upon your Majesty, upon your Majesty's House, and upon the Nation.

"In common with the rest of your Majesty's subjects, we admired the great attainments, the high character, and the noble aims of the Prince who has been taken from your Majesty and from the country so suddenly, and so grievously. We felt that the Duke of Albany was walking in the footsteps of his revered father; we had hailed with delight his apparently established health; and we hoped for a long continuance of those powers which every year seemed to be more and more developed in His Royal Highness.

"We believe that a judicious and true friend has been taken from literature, from science, from the arts of the United Kingdom of Great Britain and Ireland, and from the Empire, at a time when his calm judgment was not less valuable than his gentle and fostering care.

"Into the more sacred feelings of your Majesty's private life, and of the Duke of Albany's home, we dare not intrude, but we humbly tender the heartfelt sympathy of loyal subjects to your Majesty and to all your Majesty's family. We heartily pray that your Majesty may find all the consolation which a knowledge of the deep sorrow of your Majesty's subjects can impart."

This having been unanimously accepted after a verbal correction had been suggested by Dr. Lyons, the President announced that it would be signed by all the members of the Council on Monday.

The adjourned consideration of the case of D. M. O'Hara was then resumed.

Mr. Burrell read a letter from O'Hara, dated from Prescot, containing a number of rambling statements about his having been delayed in Liverpool by illness when on his way to appear before the Council, and asking that there might be an adjournment in order that he might have time to prepare his defence, which he assured them would afford a complete answer to the charges against him. Amongst other things, he undertook to perform what even for him would have been a feat of no small magnitude, viz., to produce the real O'Hare, whom he asserted to be in America. The letter denied by implication that he had been in London on Wednesday last.

The first witness was Mr. Wynne, whose evidence was to the effect that, in consequence of his application to Mr. Needes, O. P. O'Hare came to him as assistant in the latter part of 1882, and remained altogether with him about ten months. When he first came, he produced some printed testimonials, which seemed satisfactory. About six days after he came a death occurred, and O'Hare signed the certificate "O. P. O'Hare," which was refused, as his name was not on the Register. He then substituted the name of D. M. O'Hara, and the certificate was accepted, though this name was equally absent from the Register. [We may here correct an error into which we fell last week in saying that both these names had been removed from the Register in 1882. The real facts are that O. P. O'Hare was struck off in 1874, having been convicted of forgery in Belfast, and D. M. O'Hara was struck off in 1878 for not answering the circular.] The witness had seen the alteration in the counterfoil, but had never seen the certificate itself, and could not say how it came to be accepted by the Registrar. From the date of his signing this certificate he was always called and signed himself "D. M. O'Hara," but he continued to send goods from a draper's to some one in Belfast of the name of O'Hare, and this he had done since he had been at Prescot. He had left his employment because he owed him (Mr. Wynne) 160*l*. He went to assist a doctor in Prescot after this, and then had charge of the workhouse there, but this he had given up some months ago. The O'Hara who was recently at Prescot was the same person as the man who had been his assistant, and from what he had said at different times he inferred that the real D. M. O'Hara was dead. The next witness was the clerk to Mr. Needes, who said that he had known O'Hare on and off for about four years. In October, 1882, he saw him write the letter dated from Fleet Street, a copy of which had already been put in. He had then gone up to Liverpool to assist the last witness, and letters had been received from him after his arrival there. On Wednesday last he had called at their office to see about selling his practice; this man, who then called as O'Hara, was the same man witness had formerly known as O'Hare. He had never asked to see his diplomas.

Mr. Quinn, a Liverpool solicitor, was the next witness. He said that a man calling himself O'Hara had come to his office in November, 1882; he was not personally known to him, but he mentioned the name of a client as introduction, stating that he wished to be reinstated on the Medical Register. He said he had formerly practised in Ireland, but had gone to Australia owing to ill-health. Witness described the man O'Hara in much the same terms as previous witnesses had. The witness had obtained the papers for him from Dublin, and forwarded them to him to fill up. On that day fortnight he had gone over to Prescot for the purpose, and had seen O'Hara, who was then quite well.

The Council then deliberated in private, and it was subsequently announced that their decision was to the effect that this man had been fraudulently restored to the Register, and that it had been proved to the satisfaction of the Council that he was O'Hare; the name would, therefore, not be allowed to remain on the Register.

In the case of William Story, struck off on a conviction for arson, the Council did not accept the recommendation of the Executive Committee, having received evidence which had not been submitted to that body, and they therefore declined to reinstate him on the Register, or recommend that his licences should be restored to him.

The next business on the agenda was Dr. Haldane's motion, "That the Scottish Corporations' Joint Scheme be received and entered on the minutes." After some opposition on the part of Sir Henry Pitman, who was unable to find a seconder to his amendment, the resolution was carried.

Dr. Haldane then moved, "That the proposed co-operation between the Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow be approved of." We may mention that by a misunderstanding he made his speech on this subject on the previous resolution, but the proceedings were a little mixed at this juncture. He said that the Corporations had been willing to go forward for some time, but the Universities were not; and it had to be borne in mind that whereas in England the Universities played a very small part in medical education, in Scotland, on the other hand, the Universities did the bulk of the medical teaching. Under these circumstances the scheme before them had been drawn up, and he hoped the Council would approve of it. The object was to prevent a man obtaining a licence to practise on a single qualification, and the Corporations would refuse to give a single qualification to any one who did not already possess one. By this scheme, which had been founded on the recommendation of the Council, the examinations would be much more equalised. The only objection that could be raised was that the time was inappropriate in reference to the Bill now before Parliament.

Dr. Struthers seconded the motion, but reserved his remarks.

Mr. Simon said that for twenty-six years the Council had been formed, and during that time there had been plenty of time for such a motion, but it had never been made. At the present time it was particularly inopportune.

If the Bill became law, then there would be a combination of all the examining bodies. If the motion was now passed, it would be used against the Bill. He urged strongly that this scheme should be deferred till the Council assembled after the present Session of Parliament. If the Bill did not pass, then such a partial combination would be welcome if there was nothing better proposed.

Dr. AQUILLA SMITH took very strong objection to one paragraph in the scheme, by which the agreement was to last for five years, but might be terminated by either of the contracting parties on a year's notice being given.

Mr. MACNAMARA said the question was, whether they should endorse the Conjoint Scheme in a partial form. Mr. Simon's objection told both ways: if they passed this scheme, it might be used by the opponents of the Bill; if they did not pass it, the fact would be used by the adherents of the Bill. He denied that the Council was in a moribund condition, their legal powers were as full, and they were endowed with as much vitality as when first instituted. Duties had been imposed upon them by Act of Parliament, and to reject this scheme would be unworthy of them. It had been brought forward in perfect good faith, and he hoped they would not object to it on the ground of the impending Medical Bill. The Bill might pass, or it might not: he hoped it would, with some modifications: at present it had not the remotest ghost of a chance of passing. The scheme before them ought not to be rejected upon a side issue.

The further discussion on this subject was adjourned till Monday.

SIXTH DAY—MARCH 31ST.

The Scottish Corporations' Conjoint Scheme.

The first hour was occupied by the Council in receiving a report from their legal advisers in reference to the case of D. M. O'Hara.

The adjourned consideration of Dr. Haldane's resolution was then proceeded with. The Rev. Dr. HAUGHTON said that only three of the clauses of the scheme before them dealt with questions of principle, the others relating to matters of detail. The three included the first two, which he should support, and the last, which he should oppose. He thought the two former were a move in the right direction, on lines the Council had always urged. The Scottish Corporations had brought forward a scheme which could be easily carried out, but Clause 15 was a fatally weak spot, as there was no guarantee that the useful reforms, when once entered upon, would be continuous; he, therefore, suggested the addition of some words to this clause to render the sanction of the Council necessary to any party withdrawing from the scheme when once in working order.

Dr. QUAIN spoke in favour of postponing the resolution. His objection to the proposal was that it was altogether new, that it implied that the Council thought the Bill would not pass, and that the passing of it would be taken as an expression of the Council against the Bill. The resolution, moreover, was entirely opposed to previous resolutions of the Council in favour of a conjoint scheme, passed thirteen years ago, when the Universities were requested to take steps to form a conjoint board, and to report the scheme to the Council.

Sir HENRY PITMAN moved an amendment to the effect that the question of approving this scheme be not considered during the present session of the Council. He said that the Council ought to be very careful what they did at the present time. The College of Physicians had for years been trying to bring about a conjoint scheme, and fourteen years ago all the corporate bodies had spoken in favour of it. Referring to Lord Ripon's Bill, he said it had been approved by the Council and corporate bodies, but was opposed by the profession. Both last year and again this year a Government Bill had been introduced; the corporate bodies and the Council had failed to settle the matter, and so the Government had taken it up. They ought not to sanction any scheme which was directly in opposition to the Government Bill; this scheme was in such opposition, in that under the new Bill all licensing powers would be altogether taken away. The English scheme had been introduced to show its real date which was before the Bill of last year was brought into Parliament. He hoped that the motion would be withdrawn, as the Government would have an opportunity of seeing that there was an earnest wish on the part of the corporate bodies to act if their Bill failed.

Professor HUMPHRY seconded the amendment, and in doing so, he said that he expressed no opinion whatever on the merits of the Bill, and no opinion whatever on the merits of this scheme, or as to the effects it might have in regard to that Bill, but he seconded the amendment, because this scheme would be invalid if the Bill passed. They could enter upon the consideration of this scheme, only upon the supposition that the Bill would not pass. It would be most discourteous of the Council to enter on the consideration of this proposal, they would be putting themselves into antagonism with the Government. Another point was, that they were asked to approve this scheme or not, as it stood, some details they might object to, but only the Corporations could alter or modify it. If the Council did approve it, they would be binding the Corporations to adhere to it. They ought to await the event of the Bill, if it passed, there was an end of the matter, if it did not, it would be the duty of the Council to assemble at once, and no longer to hesitate or wait, but take up this subject without delay.

Dr. MATTHEWS DUNCAN then made a speech which referred almost entirely to the Government Bill, and not to the question before the Council. He ardently hoped and felt certain the Bill would not pass; the profession were not in favour of it, and he characterised the statement made by a former speaker, that the Council approved the principle of the Bill as entirely false. The principle of the one portal system was the worst that could be invented. Lord Carlingford's Bill would not produce peace, their difficulties would only be beginning if the Bill were passed. The one portal system was to bring about uniformity and equality, what they required was exactly the opposite; a diversity such as existed at present was beneficial. He certainly did not desire uniformity in his own specialty. Medical science and medical education had prospered during the time of dispeace; the dead stillness of uniformity did not lead to advance. He thought there was a real grievance n England, in the difficulty of obtaining the degree of M.D. The inequality of medical boards had made medical education rise; so long as they were above the lowest level, the more unequal they were the better. He had sat upon a great many boards, and thought the Universities ought not to be made to bring down their standards. The alliance between the Universities and the Corporations he described as an unholy one, they never could co-operate cordially or equally, they had utterly different objects in view, the one looked after medical matters solely, the other had very little to do with them, except in regard to their degrees. If this Bill passed he should for the first time in his life be ashamed of his profession. All the speakers had said that Dr. Haldane's scheme was a good one, that greatest object, that none should get qualified in one branch only, was provided for.

Mr. SIMON rose to object to Dr. Matthews Duncan's assertion that a statement of his was entirely false, whereupon Dr. Duncan withdrew the expression and substituted for it "misleading and inaccurate."

At this point the sitting was adjourned for a short time; on reassembling, the PRESIDENT hoped that speakers would confine themselves as closely as possible to the amendment, and avoid the Government Bill.

Mr. MACNAMARA said that he had not heard a single argument against the scheme, except in reference to the Bill. The Scottish bodies were acting within their rights, and endeavouring to discharge their duty.

Professor STRUTHERS characterised the amendment as a high-handed attempt to arrest discussion. Hardly any more important proposal had ever been brought before the Council than the present one. It would put an end to all the evils that had been complained of in Scotland. Was this amendment fair to those who brought it forward? What good purpose could be served by refusing to discuss it? He denied that the scheme was either partial or inopportune. As he could not speak to the motion but only to

the amendment, he was prevented from speaking on behalf of the Universities and Corporations; in reference to the former he had a most interesting and important communication to make; but if the amendment was accepted, he should be precluded from making it altogether. He would have been able to show that Scotland was above reproach, and had removed all occasion for legislation. He expressed no opinion about the Bill; if this scheme was passed, there would be no need of the Bill for Scotland. He denied that if the Bill did pass this scheme would be annulled; it would be in no way interfered with.

Dr. PETTIGREW hoped that the amendment would not be carried, and that there would be a discussion on the proposal.

Mr. TEALE would have been glad if they could have given a general approval of this scheme without sanctioning it. If they discussed this, they ought with it to have discussed the English scheme. Dr. Struthers had stated that the passing of the Bill would not interfere with the working of this scheme, and this would prevent him from voting for the amendment as he otherwise would have done.

Dr. HERON WATSON thought that the Council ought to consider the very carefully planned scheme brought before them. It had been asked why they had not done something of this kind before, instead of waiting 26 years, but the fact was that in 1858 a Scottish Conjoint Scheme had been formed, and had been in working order ever since. They were now trying to amend that scheme and reduce the five corporation portals in Scotland to only one. They were abundantly justified in coming forward at the present time, they could not go back if this scheme were approved. If they waited till the end of the session they could not consider the scheme till September, whereas if passed now it would be in working order by October.

Dr. BANKS believed the motion was a step in the right direction, and he regretted that Ireland had as yet done nothing in the matter. If the three kingdoms had all had such a scheme as this in working, there would never have been a bill at all.

Dr. SCOTT ORR should vote against the amendment. It had been found impossible to amalgamate the Universities and Corporations. This scheme would do away with a scandal. As to waiting for legislation, how long were they to wait? There had been three Bills in Parliament since 1870.

Sir HENRY PITMAN having briefly and forcibly recapitulated the arguments in support of his amendment, the Council divided, when the amendment was lost by a majority of two votes.

The debate on the original resolution was then resumed.

Dr. HERON WATSON explained that Clause 15, which provided for a plan by which either of the contracting parties could withdraw from the scheme by giving a year's notice, was merely a piece of legal phraseology necessitated by the Scottish customs in matters of co-partnery. There was, however, no objection to Dr. Haughton's amendment, which he was quite willing to accept.

Dr. STORRAR asked if there was any plan in contemplation for conducting the preliminary examination in arts, similar to that in England. This examination in arts should be conducted by some public body wholly outside the medical profession. The College of Physicians had long ago, and the College of Surgeons had more recently, given up holding this examination themselves. In Scotland this examination was at present conducted by the medical bodies, which was much to be regretted. He thought that they ought to have some indication from the promoters of this scheme that the preliminary arts examination would be conducted in accordance with the wishes of the Council.

Dr. WATSON said that they meant loyally to carry out the scheme, but he admitted that there was no provision against the preliminary examination being conducted by the medical authorities.

Mr. SIMON could not support this resolution when there was a Bill in Parliament that was in principle the scheme of the Council. It would be most deplorable in the interests of higher education, if the Universities did not take part with the Corporations throughout the three divisions of the Kingdom; they need not necessarily be on the same footing. The principle had been laid down in 1870, and re-affirmed 1871 and 1878, that there should be only one sanctioning authority in each division of the Kingdom. He could not be content with a scheme which was of such a limited nature. Comparing it with the Bill, it was an inferior measure. They ought to do their duty whilst they existed, but to approve a scheme in opposition to the Government scheme was not their duty.

After some further remarks from Mr. MACNAMARA, Dr. STRUTHERS, and Mr. MARSHALL, Dr. HALDANE'S resolution was put, and carried by a large majority.

On the motion of Sir HENRY PITMAN, the Conjoint Scheme of the College of Physicians and College of Surgeons of England was received and entered upon the minutes.

SEVENTH DAY—APRIL 1ST.

The Medical Acts' Amendment Bill.

Mr. MACNAMARA proposed the following resolution:—"That this Council do resolve itself into a Committe of the whole Council, for the consideration of the provisions other than those directed to the reconstruction of the General Medical Council contained in the Medical Act Amendment Bill, as amended in Committe of the House of Lords in this present Session of Parliament." Last year he had brought forward a similar resolutiou which had been lost by a small majority, he had introduced a modification this time which, he thought, would render his motion more acceptable. The President in his address had not alluded to this notice of motion, but notwithstanding this hydropathic treatment of it, it was worthy of their consideration—he did not intend to put himself into antagonism to the Government—he would indeed try to strengthen the hands of the Government, subject to their adopting an amendment which did not affect the principle of the Bill. The General Medical Council had been abused by the journals, who twitted them with using moral suasion, ignoring the result of that suasion. The Bill was a purely journalistic one, and he denied that the medical profession were panting for the Bill at all. In regard to the question of "direct representation," a meeting of the provincial and other Fellows of the College of Surgeons in Ireland was held, when only seven were in favour of direct representation. He had never heard any other than journalistic agitation in favour of it, and he did not believe that the admission of a general practitioner into their midst would in any degree strengthen their position. The Bills that had hitherto been framed and brought in had never received the sanction of any great statesman, and he instanced Lord Palmerston's reply to Mr. Hargrave. It had been said in reference to the Bill, that the motives of the Corporations were interested—the word Corporation always suggested to the public mind the idea of jobbing. Well, the motives of the College of Surgeons of Ireland were to establish, sustain, and support their library, the finest medical one in the United Kingdom, and they had also, unassisted by the State, established an anatomical and pathological museum of great value. The Colleges of Surgeons of England and Ireland were doing incalculable services to the public. He did not propose to deal with the Bill in relation to the Council, or to the licensing powers of the Corporations. But the Bill also dealt with finance, and it made some provision for keeping up the museum and libraries, but none for the departmental expenses; his College spent 1,300*l.* a year under this head, with a fixed income of 300*l.* Where would the deficit come from? The Bill provided that all the funds of the branch councils were to be centred in the General Medical Council; if some amendment were made to that, this difficulty might be removed. The branch Council of England had a much larger income than that of either Scotland or Ireland, but if the men who registered in England, with only Scottish or Irish qualifications, were counted to those countries respectively, there would be much more nearly an equality. This was a real grievance, but it would be met by an amendment he should propose. Speaking of affiliation, he said that this as now proposed was a very different thing from that submitted to the Royal Commission. The latter had refused to sanction a scheme whereby a man, when he had passed his final examination, would be compelled to affiliate himself to one of the corporate bodies; the affiliation should

be at the commencement of his medical education, not at the close of it. He pointed out that in England 85 per cent., and in Ireland 90 per cent. were content with the single qualification given by the College of Surgeons, and never took a higher one. The very existence of the body he represented was imperilled by this Bill, as if it passed they must become bankrupt.

Mr. COLLINS seconded the motion, and he did so because the Bill had left out the two Apothecaries' Halls, thus ignoring the subject of pharmacy, which was of great importance for the general medical practitioner. On this point the branch Council of Ireland were unanimously agreed that the Bill was highly imperfect.

Dr. STRUTHERS did not sympathise with those who opposed the Bill, he should not oppose it if certain modifications were made. The Royal Commission were not unanimous in their report; he thought that the minority's report (Professor Huxley's) might be made the means of a harmonious settlement of all the difficulties; it was to the effect that, provided the Council approved the arrangements there might be more than one examining body. He was in favour of the divisional boards sending coadjutor examiners. He could not reconcile himself to the idea of sweeping away all the time-honoured and respected institutions. The new scheme would diminish the responsibility of the examiners, and do away with *esprit de corps*. The Universities were placed in an extremely awkward position in regard to this Bill, they could not be rolled into one board with the Corporations. The English Scheme of 1877 had made no provisions for the Universities taking part in the examinations; such a scheme was impossible in Scotland, where the Universities were not going to hand over all their candidates to the Corporations for examination. It would be injurious and wrong if they did so. The Universities were willing to have a divisional board, in which they would be the chief authority, and they were willing to accept outside examiners appointed by the divisional boards, and he would be very happy if they went further, for he would like to see a common board for the three Universities. But they would not consent to any scheme which required a duplicate examination; no Bill would pass which thrust another examination on the Universities. The acceptance clause, as it was called, had been very cleverly framed, but would the English Universities accept it? Unless this point was cleared up the Scottish Universities would not accept this Bill. After eulogising, at some length, the Scottish Universities and their mode of teaching, he said the Corporations ought to unite and get rid of these miserable half qualifications, and then they would be able to see what need there was for further legislation. This was not a Medical Council Bill, for the Council had never recommended to sweep away existing qualifications. He believed the Bill owed its origin to a story told by the late Dr. Parkes of the Army medical examination, when a candidate did not know where the liver was situated, but it was noteworthy that at the recent examinations all the candidates were found to be fully competent. He moved an amendment in favour of the appointment of coadjutor examiners.

Dr. QUAIN denied that the Bill had had any such origin as that suggested by Dr. Struthers; it was owing to the existence of the nineteen licensing bodies, and nothing else. It was an effort on the part of the Universities and Corporations to do away with this anomaly. The Board of Reference in the English scheme was composed by the Universities as well as the Corporations. The President of the Royal Commission had said that there were gross scandals which could not be allowed to exist, and hence the necessity for legislation. The partial amalgamations, such as were proposed, would not put an end to the nineteen licensing bodies. After reminding Dr. Struthers that the College of Physicians had been founded by the University men, he said that Scotland and Ireland were the cause of all this trouble; if they had accepted Lord Ripon's Bill, there would have been no need for the Bill now before Parliament.

The Rev. Dr. HAUGHTON said that Dr. Struthers came a year too late with his amendment. A year ago the University of Dublin had petitioned against the Bill on this point, but the Scottish and English Universities refused to join them, and it was too late now to refuse to accept the principle of the Bill, which would receive the support of both the Irish Universities in the House of Commons. He would like, however, to see better money arrangements made for the Corporations.

Mr. MACNAMARA said that last year the Government had said they would as soon give up the Bill as concede this point, which was diametrically opposed to the principle of the Bill. Those who refused to make the reasonable recommendations which he had suggested were the true enemies of the Bill.

Professor HUMPHRY said that there were two points in Dr. Struthers' remarks he would notice. The first was in reference to coadjutor examiners; he did not think that proposal would be looked upon with favour by the English Universities. They regarded the matter from a higher point of view, and did not consider their degrees as mere licences to practise. They had always guarded every privilege of that sort very carefully, and the proposal was not likely to meet with general acceptance. As to the second point, they might be willing to modify their system, or might in some degree consider themselves relieved, but the Universities would not accept this examination in lieu of their own.

Dr. HERON WATSON thought they were quite justified in discussing and expressing an opinion on the Bill. These Bills did not emanate from Scotland or Ireland; they originated entirely with the London medical journals. Turning towards the reporters' table, he said that what agreed with the scheme, and what they liked they reported; and what they did not like they burked. The Council ought not to be led away by the specious statements of journalists; he hoped they would have a reporter of their own, and publish a volume of transactions. He denied that the Bill was desired by the profession; last year between 200 and 300 petitions were presented against the Bill; but no mention of them was ever made in the medical journals. Dr. Watson concluded his remarks with an uncalled-for adulation of the medical schools in Scotland.

Dr. PETTIGREW said that the combination of the Corporations showed a spirit of progress, and if the Universities also combined, there would no longer be any need for legislation.

Dr. STRUTHERS then, by leave, withdrew his amendment, and Mr. Macnamara's motion, having been put, was carried by eleven votes to nine.

The Council then went into committee, and Mr. Macnamara repeated his remarks about the way in which, under the Bill, the money was to be dealt with. He was in favour of the money being capitalised, as proposed in the Bill, but thought that the surplus should be allotted to the Divisional Boards, not in proportion to the registrations, but according to the qualifications of those registering; these Boards should have power to apply the funds at their disposal to the departmental expenses, instead of, as was at present proposed, to the museums and libraries only.

Mr. SIMON disapproved of their having gone into committee on the Bill, and strongly deprecated the passing of any resolutions on the details of the Bill. The point raised by Mr. Macnamara seemed a reasonable one, and he thought it would be best dealt with by being informally discussed by a small committee.

After some further desultory remarks from various members, a committee was appointed to meet the following day at noon, and report to the Council at 2 o'clock.

EIGHTH DAY—APRIL 2ND.

The Money Question of the Medical Bill—The Medical Acts' Amendment Bill—The Dental Fund—The Time Limit at Examinations—Unqualified Practitioners—Conclusion of the Session.

Mr. MACNAMARA brought up the report of the committee appointed over night, to consider the money question of the Bill. The report recommended the insertion of a clause providing for the maintenence of the Corporations out of the surplus funds of the divisional boards. This was seconded by the Rev. Dr. HAUGHTON, who declared that as it stood the Bill was an inequitable one. The Irish Universities did not contribute anything to the funds, and therefore

had no claim to any of the money, and would never claim any of it.

Dr. STRUTHERS said that the University museums in Scotland were maintained solely out of the fees derived from the students.

After some remarks from Mr. MACNAMARA and Dr. QUAIN, Dr. STORRAR observed that this was not their business at all, the Council had not been consulted about the Bill, why should they pick out one single subject to express their opinion upon? Did it imply that they agreed with all the rest of the Bill? He did not see why this had been brought up at all.

Mr. SIMON pointed out that the Council were not asked to formally communicate with the Government.

Dr. STRUTHERS moved, and Dr. PETTIGREW seconded, an amendment, to substitute the word Board for the word Council in the clause of the Bill relating to the subject they were now considering. This was subsequently put, and lost.

Prof. HUMPHRY said, that Dr. Struthers seemed to think that none understood the Scottish Universities but himself; but he was mistaken, they understood them quite as well as he did. Under the Bill, the Universities would have no claim to the Board Fund derived from examinations, which was to be applied in defraying the expenses of those examinations, the expenses of the Board, and the expenses of the libraries and museums. The amount under this latter head was apportioned at a certain rate, and it was especially stipulated that the University students' fees were not to be used for this last purpose at all.

Dr. LYONS disapproved of their picking out a portion of the Bill in this way for discussion, it implied that they approved of the rest of the Bill. They would, moreover, lay themselves open to the risk of being accused of picking out one small, and not very dignified portion of the Bill, for such discussion. They ought not to compromise the Council before the Legislature, the profession, and the public by discussing only a pecuniary subject. He moved that the report be adopted that day six months. This was seconded by Dr. STRUTHERS.

The Rev. Dr. HAUGHTON opposed the amendment. The Bill as it stood was an inequitable one; they were only correcting an unintentional error which had slipped in, and which did not appear in the Bill of last year.

Dr. CHAMBERS did not approve of their discussing this question at all. When a person was dying he usually thought first of making his will, and so they ought to attend to questions of administration.

Mr. SIMON had opposed the appointment of a formal committee, and he thought the best plan for them to adopt to avoid the criticism, which had been foreshadowed by more than one speaker, would be to approve the report, and suggest to the various Corporations that they should take steps to make a representation to the Government on the subject. Dr. PYLE seconded this.

Dr. LYONS' amendment was then put and lost, and Mr. MACNAMARA having accepted Mr. SIMON'S proposal, this was put as a substantive motion and carried.

Mr. MACNAMARA then moved, and Dr. WATSON seconded, that the Council should resolve itself into committee to resume the consideration of some of the provisions of the Bill, but the Council had thought better of it since the previous day, and so this motion, which had been carried by eleven votes to nine, was now lost by five to nine, the numbers against the motion being the same each day. When this point had been thus decided a change seemed to come over the Council, the prospect of sitting for the rest of the week had been made to vanish, and from that minute everyone did his best to facilitate and not hinder the business before them.

Dr. HALDANE'S motion, "That the Executive Committee should consider whether any details of routine could be advantageously suggested for introduction into the present Bill," was agreed to without discussion.

Dr. STORRAR then moved, "That the Dental Fund should in future contribute one-sixth towards the general expenses instead of one-fourth as at present." The Dental Fund was becoming very low, and it was not to be desired that they should go bankrupt; the Council did not want to become rich at the expense of the Dental Fund, and as the English Branch Council had a large sum in hand, he proposed that they should pay the difference, leaving the General Council to contribute one-half as heretofore. The proportion of dentists on the Register was in round numbers one-sixth of the total, and he hoped his suggestion would be accepted. This was seconded by Dr. AQUILLA SMITH, and supported by Dr. QUAIN, who said that the number of dentists had not increased so fast as the medical practitioners, he considered that the dentists had always been treated with great liberality. This was carried *nem. con.*

Dr. QUAIN then proposed, that the Executive Committee be empowered to improve the structural arrangements of the Council-room as best they could. When it became known that what was in Dr. Quain's mind was to raise the floor of the room about five feet without making any alteration in the height of the room, the surprise of the members at what the Rev. Dr. Haughton, in an entertaining speech, characterised as a most astounding proposal, was perfectly genuine. Not even the opinion of so eminent an authority as Mr. Teale could reconcile them to the idea of surrendering about one-third of their cubic space. There were other considerations, too, against carrying out the suggestion; if they were going to be disbanded by the present new Bill, they might as well leave their successors to try and make the room habitable for themselves; and then, again, the property was not theirs, and they had not a long lease. Would it not be better not to waste their money and energies in trying to accomplish what many regarded as an impossible feat, viz., to convert an unwholesome room into a wholesome one? These arguments by various speakers carried the day, and Dr. Quain, who explained that he had no strong feeling in the matter one way or the other, modified his proposal into referring the matter to the Executive Committee for their consideration and report.

Dr. CHAMBERS then brought forward his motion, that at the final examination no man should be rejected on a *vivâ voce* examination, unless such examination should have lasted at least half-an-hour in the case of each examiner who found him deficient. After premising that there was a strong feeling amongst the public that the rejections were too numerous, and that the supply of medical men, especially for the poor districts, was deficient, he asked whether this was the fault of the schools or of the examining bodies. The teachers complained that good and industrious students were often rejected. It was difficult to get accurate statistics on this subject, but he instanced one metropolitan hospital where several house surgeons had been rejected. What was the cause of these rejections? The percentage of rejections varied from 47 per cent. at the examination in Edinburgh for the double licence, to 20 per cent. at the College of Physicians of London. Those in which the examiners were most limited as to time gave the highest percentage of rejections. He would free the examiner from not giving more than ten minutes to each candidate; but he might pass him in two minutes if he liked. After giving a graphic account of the mental and bodily state of a candidate just after he had been through the ordeal of a *vivâ voce* against time, he said he should be told that this scheme had always worked very well in the past; but to that he would object, in that examinations were very different now from what they were even 20 years ago, not only in extent but in quality.

Mr. TEALE seconded the motion. The large number of rejections was satisfactory in that it showed that the various bodies were not competing downwards with each other. Examinations, it should be borne in mind, were two-edged, so to speak; they spurred some men on, but others were only led into a bad style of work by them; all teachers were agreed that a large number were rejected who were good men. The College of Surgeons of England examination was a beautiful piece of machinery, its examiners were unsurpassed, and yet it plucked more good men than any other body did, owing to faults in the system. It would be for the good of education that the manner in which the examinations failed at present should be reduced to a minimum.

On the other side was a great array of speakers—Dr. MATTHEWS DUNCAN, Dr. SCOTT ORR, Dr. STRUTHERS, the Rev. Dr. HAUGHTON, Mr. SIMON, and Mr. MARSHALL. Their arguments were that it was very often possible to

reject a man in less than ten minutes if he displayed great ignorance, and several of them disapproved of any time limit one way or the other. Idleness was the chief cause of the rejections, which very often were partial, *i.e.*, in one subject only. A hard-and-fast rule of half-an-hour would be open to just the same objection as one of ten minutes. The Council had, two years previously, approved a resolution recommending a margin of time in doubtful cases.

Mr. MARSHALL, who was naturally looked to to defend the system attacked, did so with much vigour; he said that this resolution was to come into effect if the examiner was in doubt, when he would have to give the candidate an additional half hour, and if the four examiners were all in doubt they would have to give the candidate two hours' further examination. But their examiners never were in doubt, they never had the slightest hesitation as to how many marks they ought to give a man. As each man was examined in the same subject at two different tables, he practically had twenty minutes' examination in each subject. There were two reasons why house surgeons came to grief in their examinations, they had not sufficient time to read, and they took an exaggerated view of the extent of their own knowledge. A good examiner in ten minutes could find out whether a man was competent or not. He thought that the present time was not the one to introduce any changes, when the Bill, which had been so much vilified in that Council-room, was before Parliament; as if it passed, and he hoped it would pass, they would have to constitute new examining Boards, and could then consider any schemes sanctioned by the Council.

Dr. WATSON said, that at the College of Surgeons in Edinburgh men were examined *vivâ voce* for forty minutes in the more important subjects, and for twenty minutes in the less important ones.

Dr. LYONS appealed to Dr. Chambers to withdraw his motion; he should be very sorry to see it negatived, and he thought a great deal had been gained by the debate which had taken place upon it. By leave the motion was then withdrawn.

A communication from the Liverpool Medical Defence Association having been received, Dr. CHAMBERS moved a resolution, to the effect that the Executive Committee should make a representation to the Government on the matter of the employment of unqualified men by registered practitioners, which, having been amended in form by Mr. SIMON, was carried.

The only other business that calls for notice, was the reappointment of Dr. Acland as President from the 18th of July next, if the Council were not sitting at the time, until their next meeting. The reasons for this step were very clearly put by Sir HENRY PITMAN, and it was at once agreed to.

The PRESIDENT, in reply, briefly alluded to their position in regard to the Bill. If it passed they would have some formalities to go through in handing over their work to their successors; if it did not pass, it would be their duty to meet in the autumn, and seriously consider what steps they ought to take when five successive Bills introduced by different Governments had failed.

After they had all thanked each other for the way in which they had performed their respective duties, the minutes of the meeting were read, and the Session was at an end.

MEDICAL NEWS.

MEDICAL SICKNESS ANNUITY AND LIFE ASSURANCE SOCIETY.

Meeting of the Provisional Executive Committee.

AT a meeting of this Committee, held on 27th ult., the secretary presented his report, showing a total of 333 members, and receipts of the preliminary entrance fees, &c., to the amount of 228*l.* 2*s.* 6*d.* A communication was read from Mr. Gilbert Walker, the editor of the *British Journal of Dental Science*, raising the question whether dental surgeons or dentists, either qualified or unqualified, or both, would be eligible as members of the Society. The question, which was thought to be an important one' was discussed at some length, and the following resolution, proposed by Mr. Sibley, was unanimously passed: "That any qualified registered dentist, holding the diploma of L.D.S., of the Royal College of Surgeons of England, Scotland, or Ireland, be eligible as member of the Society." The Secretary was desired to forward a copy of the resolution to Mr. Walker, with a request that he would bring it before the notice of the dental profession, through the columns of the *British Journal of Dental Science*. Other business was disposed of, and the meeting adjourned.

DEMONSTRATION OF PATHOGENIC MICRO-ORGANISMS.

A VERY distinguished audience assembled at the Parkes Museum, on Thursday evening, March 27th, to witness Mr. Watson Cheyne's "Demonstration of Pathogenic Micro-Organisms." The chair was taken by Sir Joseph Lister, Bart. After stating that the great group commonly called bacteria might most conveniently be sub-divided into four classes:—(1) Micrococci (round bodies), (2) Bacteria (small oval or rod-shaped bodies), (3) Bacilli (large rod-shaped bodies), and (4) Spirochætia and Spirilla (rods spirally twisted), and dwelling on the great variety as well as importance of the various parts played by this great group in the economy of nature, Mr. Watson Cheyne demonstrated numerous micro-photographs taken by Dr. Robert Koch, as well as some drawings, by means of a lime-light apparatus. He observed that great differences existed among the various bacteria in their behaviour towards the human body, some could be injected without causing any injury, others could not grow in the living body, but could develop in dead portions of tissue, and the secretions of wounds, giving rise to poisonous products. The true pathogenic organisms were able to attack the living body and multiply in it; they included the organisms which found entrance through some wound giving rise to the traumatic infective diseases; and others which could obtain entrance without any observable wound. Further, certain organisms, such as the *b. anthracis*, were capable of growing outside the body in dead organic substance, while others, such as the *b. tuberculosis* were apparently only capable of development in the living organism or under artificial conditions which reproduced to some degree those existing in the tissues of warm-blooded animals, though capable of long retaining their vitality in the dry state. With regard to the traumatic infective diseases, he thought that the most absolute proof had been furnished that the bacteria found in them, and nothing else, were the causes of these diseases; to establish such a proposition it was necessary that an organism of a definite form, and with definite characteristics, should always be found in the blood or in the affected part; the blood or the affected part when inoculated into another animal of the same species must produce the same disease; when the blood or the affected part was inoculated on a suitable soil outside the body the micro-organisms grew and must be indefinitely propagated in similar soil. When in this manner the organisms had been separated from the remains of the materials in which they were imbedded, their inoculation in an animal must produce again the same disease. the same organisms being found in the diseased parts, These conditions had now been fulfilled with regard to anthrax, septicæmia of the mouse, erysipelas, tuberculosis, glanders, and acute pneumonia. With regard to typhoid fever, relapsing fever, cholera, and ague, the evidence was very strong, but not conclusive. Mr. Watson Cheyne concluded by dwelling on the importance of surrounding circumstances, chiefly those summed up in the phrase, unhygienic conditions, as concomitant causes of disease by preparing the blood for the attacks of these micro-organisms.

The Chairman, Sir Joseph Lister, dwelt upon the important fact that the organisms which produced particular diseases were only able to develop under very special conditions, instancing the bacillus, which caused septicæmia in the house-mouse, but which was unable to produce any deleterious effects on the field-mouse. He thought this fact, which showed that the very slight difference in the

blood of these two animals was sufficient to alter the conditions favourable to the development of the bacteria, might prove of very great interest, as it was possible to conceive that by the administration of some medicines, sufficient alteration might be produced in the blood of the human system to kill off, or to prevent the development of, any special bacteria, on the first appearance of the symptoms of the disease in the patient. Sir Joseph Lister concluded by referring, at some length to the importance of Pasteur's researches on modified virus.

Prof. Humphry paid an eloquent tribute to the great work which Sir Joseph Lister had already achieved, and looked forward with great hopes to the future of medicine.

Royal College of Surgeons of England.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Board of Examiners on the 1st and 2nd instant, and when eligible will be admitted to the pass-examination, viz. :—Messrs, H. E. Hackett; A. B. Crowther; Harry Harrop; George O'Kill; J. M. Johnson; N. C. Haring, and W. K. Walls, Manchester. Henry Skelding; E. C. Andrews; William Clarke; Charles Brook; E. P. Manby, and B. de B. Carey, F. M. Ogilvie, Cambridge. F. W. Halliday; C. W. Turner; C. F. M. Althorp; F. W. Thornton; H. A. Smith and Harold Hebblethwaite, Leeds. F. W. Bloomer; A. H. Nott; G. L. Hill, and J. H. Blakeney, Birmingham. G. A. Syme, Melbourne. W. F. Brook and Ernest Solly, St. Thomas's Hospital. D. P. Gaussen and W. G. Bigger, Belfast. O. P. Beater, Dublin. John Girling, London. B. B. Grayfoot; David Hepburn and J. M. Caw, Edinburgh. J. W. Dalgliesh, Newcastle-upon-Tyne. J. H. Abram; John Cunningham, and A. A. Kanthack, Liverpool. W. L. Dickinson, St. George's Hospital. W. C. Swayne, and R. F. W. Tucker, Bristol. Seven candidates were referred for three months.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 27, 1884 :—

Aspinall, John, Ash Cottage, Hindley.
Averill, Charles, Stafford.
Caleb, Clement Cornelius, Allahabad, India.
Cropley, Henry, Swaton, Lincolnshire.
Davis, Edwd. Sandom Stone, Fowey, Cornwall.
Forster, Thos. Fredk., Brampton, Cumberland.
Freeland, Freeland John, Antigua, West Indies.
Hopkins, Jno. Walter, The Infirmary, Ryde.
Leech, Priestley, Linden Road, Halifax.
Moore, Edwd. Head, Falmouth.
Paul, Edmund Wm., Wearne Wyche, Langport.
Stericker, Geo. Fredk., Pickering.
Woolmer, Shirley Lawrence, The Poplars, Kingswood, Bristol.

Army Medical Department. — Deputy-Surgeon-General R. Wolseley has been ordered to Aldershot to assume the duties of Divisional Sanitary Officer in succession to Deputy-Surgeon-General J. J. Thompson, who will proceed to Dublin for duty as Principal Medical Officer of that district. Surgeon-General W. A. MacKinnon, C.B., has been appointed a member of the Committee on Movable Field Hospital Equipment.

Army Medical School, Netley.—The 48th Session of the Army Medical School was opened on the 2nd instant, when 21 gentlemen joined for the Home Service, and five for the Indian. The introductory address was delivered by Professor Maclean, who began with a graceful and touching allusion to the death of the Duke of Albany. The Professor welcomed the new surgeons on probation, and explained the objects of their sojourn at Netley, pointing out the advantages of a military career, but warning them at the same time of the obstacles their best efforts may have to encounter, from the indiscriminating blame sometimes heaped upon the Department, for shortcomings for which it ought not to be held responsible. He illustrated this by the experience of Robert Jackson in former days, and by the unmerited obloquy thrown upon the medical officers in the Egyptian campaign of 1882. The Professor wound up a most eloquent address with an expression of hope that the stay of the surgeons on probation at Netley might be both profitable and pleasant. Surgeon-General Murray and the medical and professional staff were present, as well as Dr. Dayman, President of the Southampton Medical Society, &c. The occasion was rendered further interesting by the fact that it is the first time that the school has been opened at Netley since the post of Governor and Commandant of the Royal Victoria Hospital has ceased to be. From this time forth the Surgeon-General is sole responsible and administrative head of the establishment, and a galling and vexatious grievance has been at length removed. The excellent results which have followed a similar change in the hospitals of the Royal Navy are not likely to be wanting at the head-quarters of the sister service.

Anderson's College. — The winter session of the Medical School was brought to a close on the 27th ult. with a distribution of prizes in the theatre of the institution.

University College Hospital.—At the annual general meeting of subscribers, held on Monday, it was stated that the year had closed with a debt of 8,500*l*. This being the jubilee year of the hospital, a great effort will be made to place the funds upon a more satisfactory footing, and with this object in view the Lord Mayor has consented to preside at a public meeting to be held at the Mansion House on June 16th, when several distinguished personages will attend in support of the appeal for funds.

The Johns Hopkins Hospital, Baltimore.—Already 2,400,636 dollars have been spent upon this hospital, and it is estimated that 400,000 more will be required for its completion. It is expected that it will be opened before October, 1886.

The Grosvenor Hospital for Women and Children. —This small hospital, hitherto known as the "Vincent Square Hospital," has been in some measure reorganised, and henceforth, with the concurrence of the Duke of Westminster, will be known as the "Grosvenor Hospital." The annual meeting was held on Friday last, under the presidency of Lord Shaftesbury.

Abernethian Society, St. Bartholomew's Hospital. —At the annual general meeting of this Society on March 20th, the following gentlemen were elected officers for the ensuing year:—Presidents, Dr. W. J. Collins, Mr. T. W. Shore. Vice-Presidents, Mr. N. J. Collyns, Mr. C. O. B. Harding. Hon. Secretaries, Mr. C. P. Crouch, Mr. A. Lyndon. Additional Committeemen, Mr. F. Andrews, Mr. H. Huxley.

Death from the Bite of a Monkey.—Last week an inquest was held on the body of Captain G. Butler, aged 68, who had died in University College on the 28th ult., from blood-poisoning, following the bite of a monkey, inflicted three weeks previously. The deceased was suffering from diabetes, and the wound was gangrenous when he was received at the hospital.

Small-pox in India.—Small-pox continues to rage with great violence at Madras, and for some time past the weekly mortality returns have shown a death-rate from small-pox and other causes of about 85 per 1,000 per annum. The mortality is mainly among unvaccinated children. An act making vaccination compulsory has been passed by the local council, and the Viceroy's assent obtained by telegraph. It is hoped it may have the effect of checking the disease. Small-pox is also causing great mortality in Rangoon, and in several cities of Upper India. It is described as above the average in Calcutta, and appears to prevail to a greater or less extent in almost every large city in the country.

Death from Chloroform.—A death from chloroform is reported from Portsmouth. The anæsthetic was administered on a Skinner's inhaler to a middle-aged man, a portion of whose tongue was about to be removed. The inhalation lasted six minutes, when the patient became suddenly pulseless, and all the measures taken to restore life were ineffectual.

Hird Testimonial.—The testimonial, consisting of a service of plate, which has been subscribed for by the friends of Mr. Francis Hird, will be presented to him at the Charing Cross Hospital Medical School, on Tuesday next, at 4.30 o'clock. Professor Huxley will occupy the chair.

APPOINTMENTS.

BRANFOOT, H. S., M.B.—Assistant Physician to the Sussex County Hospital, *vice* J. Rutter, M.D., resigned.

DAVIDSON, P., M.A., M.B.—Assistant Medical Officer to the Infirmary for Children, Liverpool, *vice* J. McClelland, M.D., promoted.

EDINGTON, J. E., M.R.C.S. Eng.—Medical Officer to the Brandes Burton District, Skirlaugh Union.

FITCH, R. A., M.R.C.S.—Resident Surgeon to the Birmingham General Dispensary, *vice* Harry Green, M.R.C.S., resigned.

HARPER, GERALD, M.B.—Assistant Physician to the Chelsea Hospital for Women.

JACKSON, A., M.R.C.S.—Assistant House Surgeon to the Hull General Infirmary, *vice* E. F. Potter, M.R.C.S., resigned.

MOULLIN, C. W. MANSELL, M.D. Oxon, F.R.C.S.—Demonstrator of Anatomy at the London Hospital Medical College, *vice* Mr. Treves.

RUTTER, J., M.D.—Physician to the Sussex County Hospital, *vice* E. F. Fussell, M.B., resigned.

TOVEY, R. N., L.R.C.P. Edin., L.F.P. & S. Glas.—Medical Officer to the Knightwick District, Martley Union.

WHARRY, R., M.D.—Physician to the Westminster General Dispensary.

WINDLE, C. A. B., M.D., B.Ch. Dublin.—Resident Medical Officer to the General Hospital, Birmingham, *vice* J. W. Bond, M.D., resigned.

VACANCIES.

CASTLE WARD UNION.—Medical Officer for the Whatton District, in succession to Mr. M. Walker, resigned. Area, 16,981 acres. Population 1,273. Salary, £15 per annum.

CHESTERFIELD UNION.—Medical Officer for the Eckington District, in succession to Mr. J. T. Jones, resigned. Area, 8,673 acres. Population, 13,935. Salary, £40 per annum.

DEVONSHIRE HOSPITAL, BUXTON.—Medical Officer. (*For particulars see Advertisement.*)

DURHAM COUNTY HOSPITAL.—House Surgeon. Salary, £100 per annum, with furnished rooms, coals, and gas. Candidates' names must appear on the Medical Register, as being possessed of a Medical and Surgical Qualification, and they must produce evidence of good moral character. Private practice prohibited. Applications, with testimonials, to be sent to the Honorary Secretary, 10, South Bailey, Durham, on or before April 15th.

FLINTSHIRE DISPENSARY.—House Surgeon. Salary, £100 per annum, with furnished house, &c. Candidates' names must appear on the Medical Register, as being possessed of Medical and Surgical qualifications, and they must produce evidence of good moral character. Private practice prohibited. Candidates conversant with the Welsh language preferred. Applications, with testimonials, to be sent to the Secretary, on or before April 15th. The election will take place on April 30th.

GREAT NORTHERN CENTRAL HOSPITAL, CALEDONIAN ROAD, N.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)

JARROW PROVIDENT DISPENSARY.—Qualified Practitioner. (*For particulars see Advertisement.*)

LICHFIELD UNION.—Medical Officer for the Yoxall District, in succession to Mr. Greenwood, resigned. Area, 7,780. Population, 1,684. Salary, £25 per annum.

LINCOLN UNION.—Medical Officer for the Sixth District, in succession to Mr. H. Gilbert, resigned. Salary, £25 per annum.

MORPETH DISPENSARY.—Resident Medical Officer. Salary, £100 per annum, with furnished apartments, coals, and gas. Candidates must be duly qualified, and unmarried. Applications and testimonials to be sent to Mr. D. W. Greenwood, Morpeth, on or before April 5th.

ROYAL FREE HOSPITAL, GRAYS' INN ROAD, W.C.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)

SEVENOAKS UNION.—Medical Officer for the First and Fourth Districts, in succession to Mr. R. M. Rathill, resigned. First District—Population, 194. Salary, £75 per annum. Fourth District—Area, 13,538 acres. Population, 5,013. Salary, £100 per annum.

STRATTON UNION.—Medical Officer for the South District, in succession to Mr. J. H. Tuke, resigned. Area, 27,430 acres. Population, 2,907. Salary, £60 per annum.

THE BIRMINGHAM AND MIDLAND COUNTIES ORTHOPÆDIC AND SPINAL HOSPITAL. Honorary Assistant Surgeon. (*For particulars see Advertisement.*)

DEATHS.

COE, THOMAS, F.R.C.S., at 71, Guildhall-street, Bury St. Edmund's, on March 26th, in his 67th year.

HARDING, JOHN, M.B., at 54, Lancaster-road, on March 19th, aged 75.

LASHMAR, C. M., M.D., formerly of Croydon, at Dover, on March 28th, in his 81st year.

MCDONALD, T. W., I.G.R.N., F.R.C.S., at Landscore Villas, Teignmouth, Devon, on April 1st, aged 80.

SCHULHOF, MAURICE, M.D., at 46, Brook-street, Grosvenor-square, on March 27, aged 68.

THOMAS, EDWARD TEMPLE, L.R.C.S., at Chatham, on March 25th, aged 36.

NOTES, QUERIES, AND REPLIES.

THE ROGERS TESTIMONIAL.

The following Subscriptions have been received.

Dr. Danford Thomas, Coroner for Central Middlesex, £1 1*s.*; Dr. Hawkley, 31, Grosvenor Street, £1 1*s.*; G. Terry, Esq., Mills, £1 1*s.*; Dr. G. Barnes, Ewell, 10*s.* 6*d.*; Thos. Davies, Esq., Colwyer Bay, 5*s.*; A Pauper, 2*s.*

Mr. J. Wickham Barnes requests all subscribers who have not yet sent him their promised donations, to do so at their earliest convenience.

THE WHEATLEY MEMORIAL FUND.

[TO THE EDITOR OF THE MEDICAL TIMES.]

DEAR SIR,—I enclose you a list of the subscribers to the funds, so far as their subscriptions have been received. I shall be much obliged if you will give space to its insertion in your columns. The amount received is at present far below the sum required to make the needful provision for those dependent on the late Librarian of the Royal Medical and Chirurgical Society.

April 1st, 1884.

I am, dear Sir, yours, &c.,

BERKELEY HILL,

Hon. Sec., Wheatley Memorial Fund Committee.

Thomas Boone, Esq., £50; The Clinical Society, £25; Dr. William Wood, £25.

The following have sent ten guineas each:—Sir Andrew Clark, Bart., M.D.; T. B. Curling, Esq.; J. Cooper Forster, Esq.; Sir Prescott Hewett, Bart.; Berkeley Hill, Esq.; and Sydney Williams, Esq.

The following have sent five guineas each:—Morrant Baker, Esq.; J. E. Erichsen, Esq.; Dr. Wilson Fox; Dr. Gervis; Dr. Habershon; Christopher Heath, Esq.; J. W. Hulke, Esq.; Dr. Hughlings Jackson; Sir William Jenner, Bart.; Dr. George Johnson; John Kingdon, Esq.; John Langton, Esq.; John Marshall, Esq.; Sir James Paget, Bart.; Dr. Priestley; W. S. Savory, Esq.; Thomas Smith, Esq.; Sir Henry Thompson; Dr. Wegg; and Sir Erasmus Wilson.

The following have sent five pounds each:—Sir William Bowman, Bart.; Dr. Matthews Duncan; H. Cæsar Hawkins, Esq.; and Dr. Douglas Powell.

The following have sent three guineas each:—Dr. Dyce Duckworth; Alexander Shaw, Esq.; John Wood, Esq.; and Dr. Routh.

The following have sent two guineas each:—Dr. R. Barnes; Dr. Cayley; Dr. Duffin; Dr. Finlay; W. H. Flower, Esq.; J. G. Forbes, Esq.; Jonathan Hutchinson, Esq.; Dr. Stephen Mackenzie; J. H. Morgan, Esq.; E. Nettleship, Esq.; Dr. W. Ogle; Dr. O'Neil, Lincoln; T. Pickering Pick, Esq.; George Pollock, Esq.; Dr. Sieveking; John Simon, Esq.; Dr. Symes Thompson; and Dr. Charlewood Turner.

The following have sent one guinea each:—J. E. Adlard, Esq.; Dr. Appleton; John Birkett, Esq.; Dr. John Candy; Dr. Champneys; Dr. Fairlie Clarke; F. Le Gros Clark, Esq.; R. H. Clay, Esq.; Dr. Cleveland; H. Clutton, Esq.; H. Curling, Esq.; Dr. Horace Dobell; Dr. Langdon Down; Dr. Ewart; Sir Joseph Fayrer; Dr. Gowers; Reginald Harrison, Esq.; Dr. Herman; Dr. Graily Hewitt; George Knapton, Esq.; A. W. Leachman, Esq.; Dr. MacFarlane; F. Mason, Esq.; Dr. Gueneau de Mussy; Surgeon-Major Myers; Dr. T. A. Nelson; T. Niven, Esq.; T. L. Read, Esq.; Dr. F. T. Roberts; Sir Edwin Saunders; Dr. Sedgwick; Dr. Felix Semon; Dr. Sharkey; Dr. Sieveking; John Simon, Esq.; Dr. Pye Smith; Dr. Sutherland; Dr. Trend, Southampton; W. W. Wagstaffe, Esq.; C. Stuart Watkins, Esq.; H. Watney, Esq.; Spencer Watson, Esq.; Dr. Dawson Williams; Dr. Charles West; and Messrs. Wodderspoon & Co.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—In reply to Dr. Daunt's numerous questions, will you allow me to point out that a simple reference to the Medical Digest would have answered each; Section 1,756, 3, showing that electricity has been used to treat elephantiasis; Section 662, 4, pointing to the use of glonoin *vel* nitro-glycerine in asthma; Section 27, 4, establishing the value of picrotoxin in idrosis; and Section 374, 4, giving a fund of information regarding the use of hyoscyamin in various diseases.

I am, Sir, &c.,

RICHARD NEALE, M.D. Lond.

Royal College of Surgeons, Primary Examinations.—The following were the questions on Anatomy and Physiology which were submitted to the 256 candidates for the diploma of membership of the Royal College of Surgeons on the 31st ultimo, when they were required to answer four, and not more than that number, out of the six following questions on ANATOMY, from 1 to 3 o'clock p.m.:—1. Describe the dissection down to the bones of that portion of the palm of the hand which lies to the ulnar side of a line drawn from the middle of the annular ligament to the cleft between the ring and middle fingers. 2. Describe the course and relations of the veins which terminate in the inferior vena cava. 3. Enumerate the various kinds of joints met with in the human body, and give examples of each kind. 4. Describe the structures filling in an intercostal space, and give their relative positions. 5. Describe the attachments, connexions, relations, and actions of the biceps flexor cubiti. 6. Give a dissection displaying fully the external circumflex artery of the thigh and its branches.

The following were the questions on PHYSIOLOGY, to be answered from 4 to 6 o'clock p.m.:—1. Describe the excretory functions of the skin. What relations exist between these

functions and those of the lungs and kidneys? 2. Describe the different forms of peripheral nerve-endings in man, and state the functions of each. 3. What are the evidences of the circulation of the blood? State the forces by which that circulation is maintained. 4. Describe the formation of the placenta. What are the functions of this organ? 5. Describe the blood supply to the different parts of the kidney, and the relation of this supply to the secretion of urine. 6. Describe the mechanism of voice and speech.

COMMUNICATIONS RECEIVED—

THE HON. SECRETARY, WHEATLEY MEMORIAL FUND, London; Dr. H. HANDFORD, Nottingham; Mr. T. M. STONE, Wimbledon; THE PUBLISHER, AUSTRALIAN MEDICAL GAZETTE, Sydney; THE EDITOR, BOMBAY GOVERNMENT GAZETTE, Bombay; THE REGISTRAR-GENERAL, Edinburgh; THE SANITARY COMMISSIONER, Punjab; Sir EDMUND LECHMERE, London; THE SECRETARY, CLINICAL SOCIETY, London; THE SECRETARY, POOR LAW OFFICERS' ASSOCIATION, London; THE SECRETARY, NATIONAL ASSOCIATION FOR THE PROMOTION OF SOCIAL SCIENCE, London; THE SECRETARY, MEDICAL SICKNESS ANNUITY AND LIFE ASSURANCE SOCIETY, London; THE DIRECTORS, PATENT LIQUID FIRE-PROOF CYANITE CO. APPOINTMENTS FOR THE WEEK.

April 5. Saturday (this day).

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

ROYAL INSTITUTION, 3 p.m.—Capt. Abney, "Photographic Action."

7. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

MEDICAL SOCIETY OF LONDON.—Dr. Joseph Coats (Glasgow), on "Compensatory Hypertrophy of various Organs;" Dr. Clement Godson, on "Retroversion of the Gravid Uterus."

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN, 8 p.m.—Meeting, at 40, Leicester Square. Casual Communications by Messrs. Storer Bennett, J. H. Mummery, F. N. Pedley, E. Lloyd Williams; Mr. A. S. Underwood will read a Paper on "The Influence of Micro-Organisms in the Production of Caries."

ROYAL INSTITUTION, 5 p.m.—General Monthly Meeting.

8. *Tuesday.*

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 p.m.—The following Papers will be read:—John Harley, M.D. Lond., F.R.C.P., "The Pathology of Myxœdema as Illustrated in a Typical Case." One of Dr. Harley's patients with myxœdema will be present for examination. F. B. Jessett, F.R.C.S., "An Enquiry into the Cause of the Increase of Cancer in England and Wales."

9. *Wednesday.*

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

EPIDEMIOLOGICAL SOCIETY OF LONDON, 8 p.m.—Meeting. Bolton G. Corney, Esq., will read a Paper on "The Behaviour of Certain Epidemic Diseases in Natives of Polynesia, with especial reference to the Fiji Islands."

HUNTERIAN SOCIETY.—7.30 p.m.: Council. 8 p.m.: Dr. Stowers, "Sequel to a Case of Paget's Disease of the Nipple;" Mr. Rivington, (1) "Case of Recent Fracture of the Patella, treated by Wire Suture;" (2) "Case of Wound of Knee-joint;" Dr. Herman, on "Prolapse of the Pelvic Floor, without relative Displacement of the Uterus."

ROYAL MICROSCOPICAL SOCIETY, 8 p.m.—Meeting. Dr. W. B. Carpenter will read a Paper on "Binocular Vision with the Microscope."

10. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

11. *Friday.*

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

THE ÆTIOLOGY OF PHTHISIS.

Being the Lumleian Lectures Delivered at the Royal College of Physicians,

By J. ANDREW, M.D., F.R.C.P.,
Physician to St. Bartholomew's Hospital.

Lecture I.—[Abstract.]

The lecturer said that he should not attempt an exhaustive treatment of so vast a subject as the ætiology of phthisis, but would regard it from one comparatively narrow point of view, viz., the communicability of the disease immediately or mediately from the sick to the healthy. Was phthisis contagious or not? He would at once confess himself to be an anti-contagionist, and admit that his argument must have been more or less biassed by its being framed rather to attack a given proposition than to establish any other in its place. This question of contagion, indeed, wherever it arose, whether in the case of phthisis or of other diseases, had rarely been discussed with judicial calmness. At the very outset of the enquiry it was necessary to give a definition of phthisis—to state the sense which he himself attached to the term. By phthisis, he meant a specific disease, characterised, anatomically, by a new growth, which might wear very different aspects at different periods of its existence, and in different organs or tissues, especially, according as it was found in the interior of organs, or as it presented upon a free serous, mucous, or cutaneous surface. The new growth might occur in almost any organ or tissue, but did so most frequently in the lymphatic tissues and in the lungs. Generally it proceeded from numerous different points, the growths from which might or might not coalesce, thus leading, *e.g.*, in the lungs to two different types of lesion, viz., miliary tuberculosis, and to more or less extensive areas of infiltration and consolidation. Further, in the case of the lungs, this new growth did not follow the general law of distribution or localisation of pulmonary diseases. It had some special affinity for the apices, and descended in levels, attacking the upper portion of the lower before it had reached the base of the upper lobes. It killed by the disturbance and disorganisation which its presence worked in some vital organ; its clinical history was that of a general rather than that of a local disease; the constitutional symptoms, especially in the earlier stages of the disease, bearing no definite relation to any ascertainable structural lesions. He believed, in short, that consumption, phthisis, or tuberculosis was a specific disease, occurring in both acute and in chronic forms; that it was not a mere catarrhal inflammation, a peribronchitis, a chronic apex-pneumonia, but a disease as distinct in its nature as scarlatina, or as gout.

The recent discovery of the tubercle-bacillus had added to the old stock of arguments a fresh fact of the utmost importance, and had been looked upon by many

as a conclusive proof of the doctrine of contagion in its most extreme form, while a strong tendency had been shown to treat the older views and observations with contempt. In order to estimate the influence of our knowledge of the bacillus upon the doctrine of phthisis, he would endeavour, first, to state the position of that doctrine with the value of the facts on which it was based, prior to Dr. Koch's discovery; and secondly, to discuss the modifications which that discovery might render necessary in the older views.

Dr. Wm. Budd, of Clifton, in his famous Memorandum on Phthisis, had stated certain striking facts, and had quoted authorities to show that in the case both of the South Sea Islanders and the native American Indians, phthisis was unknown until the aborigines came into intimate contact with Europeans, while in the case of the negro races of Africa, the disease was very fatal on the sea-board when the blacks had come into intimate relations with the whites, but did not exist in the interior. It was impossible, however, the lecturer said, to establish these statements. The oft-quoted authority of Dr. Rush, when analysed, was very far indeed from being decisive of the question of the importation of phthisis into North America. He gave not the slightest hint of believing in its foreign origin, but regarded it, even in its incidence on the whites, as one of the results of advancing civilisation. Moreover, phthisis might easily exist among barbarous races, and escape the notice of even the most competent observer. A savage stricken with phthisis would rarely live to develop the later and more striking features of the disease. The value of his life in the earliest stage would be a vanishing quantity, like the "prairie value" of land. With the first serious failure in strength of lung or of muscle, the struggle for existence would be promptly decided against him. And thus civilisation, with its care for the sick and weakly, would sometimes appear to have introduced that which it had only preserved, and, so to speak, cultivated. An almost necessary consequence of this artificial survival of the unfit would be the spread of the phthisical taint, in virtue of its hereditary character (to say nothing of the unwholesome influences of a nascent civilisation), and a great increase, both absolute and relative, in the number of cases of phthisis. In the Pacific, the first European visitors of many of the islands were certainly not persons well qualified to conduct a very difficult scientific enquiry, and there were many statements on either side. A friend, a member of the Melanesian Mission, who had known many of the islands well for some years past, assured him (the lecturer) that he believed consumption to have existed among them before the arrival of Europeans. Again, in the case of Africa, although very few white men penetrated into its interior, regular caravan routes had existed for ages, by which any disease so contagious as some believed phthisis to be must have been spread over the whole interior, even before the time of the Romans. Thus, the distribution of phthisis in Africa, its prevalence on the coast, and its rarity inland; its being confined to certain parts only of wide regions traversed for centuries by largely used trade routes, was a strong argument, not for, but against, its contagiousness. Moreover, in other countries to which phthisis had been long known, and where no question of restricted intercourse arose, it still prevailed to a much greater extent near the sea than in the interior.

Granted, however, for the sake of argument, that it could be established as a certain fact that phthisis had made its appearance among a certain number of savage tribes after the arrival of Europeans, and that it was unknown before that event, surely the imputation of a new and specific morbific germ was not the only rational explanation which could be offered. If for the time we adopted the view that phthisis was a diathetic disease, the outcome of unhealthy conditions of life, then it was well known that the first contact of civilisation with barbarism subjected the savage to many most unwholesome influences. He was tempted to indulge to excess in alcoholic liquors, often of the vilest quality, and he forsook his old free life of hunting or fishing for one of comparative indolence. What room for surprise was there, if, under such changed circumstances, he became liable to new forms of diathetic disease? If, however, we accepted the doctrine, the true doctrine, that phthisis required for its production, not only predisposition, but also the action of an external agent, probably organic, then the supposition that the impaired vigour of the savage has subjected him to external agents, always present although hitherto impotent, was at least as plausible as that of an "imported germ." This historico-geographical argument, which had been regarded as so decisive of the whole question, was a most insidious one; lying outside ordinary medical studies, it was often stated confidently, and accepted thoughtlessly. But he trusted he had shown good reason for believing that the facts had come to us in so distorted a form as to be worse than useless; for, while they could be made to harmonise readily with either the diathetic or the contagion theory, they were absolutely worthless for the proof of either.

Turning now to the influence of certain conditions on the prevalence of phthisis, he would endeavour to indicate the kind and value of the evidence involved, and its bearing on the doctrine of contagion. Phthisis existed in all climates—tropical, temperate, and arctic—apparent exceptions serving only to bring into strong relief the much greater importance of local than of general influences. It was more prevalent in the tropics; but arctic rigors did not prevent it. At Moose, or Moosonee, a trading station on Hudson's Bay, enjoying a typical arctic climate, the statistics from 1811 to June, 1882, showed that of 162 entries of the cause of death, 68 were due to consumption, almost all occurring among the natives. On the other hand, there were tropical countries, Senegambia and the Gold Coast, where phthisis was all but unknown among the natives, but was of frequent occurrence among the West Indian soldiers stationed there, and their families, although in their own country they were said to possess an almost complete immunity from it. He believed such exceptions furnished a most useful clue to the nature of the disease. On the whole, the facts, so far as they were known, which bore upon the relation between climate and phthisis, did not justify any more distinct conclusion than this, viz., that, as a matter of fact, phthisis might and did exist in any climate, and that the influence of climate, whatever it might be, so far as it depended upon latitude was but slight, and constantly modified or overridden by other more potent conditions.

About the influence of elevation above the sea-level in diminishing the phthisis death-rate, no reasonable doubt existed; with certain exceptions, the higher we ascended the greater was the immunity from phthisis, until at last it became almost if not quite complete. But the conditions on which this result depended were by no means equally clear. His own belief was that freedom of the air from impurities was the real explanation; at certain heights, the micro-organism which excited phthisis being no longer met with. A residence at a high altitude not only prevented phthisis, but also cured many persons suffering from it.

Passing on to consider the effect of dampness of soil on the distribution of phthisis, the lecturer quoted Dr. Buchanan's report, "On the Distribution of Phthisis as affected by Dampness of Soil," published in 1867. In this it was stated as true generally, and not only of particular districts—that wetness of soil is a cause of

phthisis to the population living upon it. No other circumstance could be detected that coincided on any large scale with the greater or less prevalence of phthisis, except the one condition of soil. Some years earlier, in 1862, Dr. Henry J. Bowditch had anticipated Dr. Buchanan's conclusions, having found himself compelled by force of facts to resign the commonly received opinion that consumption was equally diffused throughout New England, and to adopt the view that there were some spots which had very little of that scourge of the human race, while in other places, and even in particular houses, it prevailed to a frightful degree; and, moreover, that these spots might be, perhaps, within a very short distance from each other. The facts indicated that dryness of the soil in their surroundings was the prominent characteristic of places comparatively free from consumption; while dampness of the soil characterised the consumption-breeding districts. The influence of dampness of the soil, however, in increasing phthisis mortality, although it rested on unusually trustworthy facts, was yet not an universal law, and the lecturer quoted exceptions to it, concluding that whatever might be the relation between dampness of the soil and phthisis, it was clearly one which might be overpowered or masked by other forces.

"Of the three conditions so far considered," the lecturer continued, "two—viz., altitude and soil-dampness—have, undoubtedly, great influence; the first in preventing, the second in developing phthisis; and, in both, the facts indicate that there is a something, in large measure independent alike of the constitution and social habits of the population subject to it, but without which phthisis cannot exist. It is certainly improbable that altitude acts by producing, sooner or later, a race of men which is proof, or all but proof, against certain morbific conditions. For, on the one hand, natives of the hills readily contract phthisis in lowlands; and, on the other hand, the lowlanders recover when removed to the hills. The anti-phthisical constitution, if it be in any way due to altitude, must be a very temporary affair, easily acquired and easily lost; and yet there is no *à priori* improbability against the formation of such an anti-phthisical constitution, or against its acquiring a permanent character. Indeed, we know that there are races which remain comparatively unharmed by phthisis in the midst of deeply infected localities, *e.g.*, the Chinese in Melbourne.

"Since, then, at a certain height above the sea, phthisis ceases to occur, and affected cases recover without affecting injuriously their friends and neighbours, whilst there is no reason to suppose that these latter possess any special protection against phthisis, other than what may be temporarily due to residence at a certain altitude, it is surely reasonable to suggest that the cause of this immunity is to be found in the supposition that some external agent, essential for the development of phthisis, is here inert or absent. In the case of soil-dampness, the probability of the existence of some such agent is even greater. It is difficult to understand in what way the drying of the soil, by the execution of sewerage-works, could have so profoundly and so rapidly altered the constitution, occupation, habits, and vitality of the people of Salisbury, for example, and of other towns, as at once to reduce, by a very large percentage, the number of cases of a developmental disease, if phthisis be recognised as developmental, or of a directly contagious disease, if it be recognised as directly contagious. Surely, here, too, as in the case of altitude, a reasonable, perhaps the best, explanation of the facts is that phthisis is produced by some external agent, but yet not spread in the ordinary course of things by direct contagion. The evidence from the effect of climate pointing in the same direction is less strong, for the affirmative facts are less certain and less striking. The exception, however, under all three heads, climate, altitude, and soil-dampness, permits even a stronger proof than can be drawn from the general laws to which they are related. It is, I believe, all but impossible to explain these exceptions on either the developmental theory or on that of direct contagion; but this will be treated of in greater detail in the final summing up of the conclusion to be drawn from the nature of the so-called causes of phthisis. At present, I would only add that these three conditions are, in themselves, entirely independent of any human agency; that, so far as man's action modifies the unwholesome influence of any one of them, it will be to minimise it by the use of suitable clothing, food, fire, and shelter, and that, therefore, their real power, as gauged by statistics, is probably under—rather than over—stated."

Lecture II.—[Abstract].

The next class of causes which had to be considered related to modes of life and industrial occupations. The difficulty of separating the influence of the day workshops from that of the homes was very great; but as the home surroundings were very similar in those obtaining the same pay in the same occupation, any great variation in the phthisis mortality might be fairly attributed to the occupation. This group he proposed to divide into two sections, viz.:—1. Those occupations and modes of life in which there was the possibility (or likelihood) that direct contagion might come into play. 2. Those in which there was no greater danger of such contagion than all of us were exposed to in the ordinary intercourse of life. In the first of these sections indoor occupations contrasted unfavourably with outdoor pursuits. In the case of trades it was impossible so ascertain the true proportion of cases of tubercular phthisis included under the head of deaths from pulmonary disease; wherever imperfect ventilation of workshops, with or without overcrowding existed, the possibility of direct contagion could not be denied. In reference to the second section, the lecturer pointed out that certain occupations gave, apart from overcrowding or want of ventilation, a high death-rate from pulmonary diseases. The chief causes seemed to be—1. The presence in the air of fine dust of any kind, of carbonic acid or other noxious gases. 2. Exposure to great vicissitudes of temperature. 3. Inhaling hot air, either very dry or very moist. 4. The workman being obliged to carry on his labour in some cramped posture, interfering with the freedom of the respiratory movements. He thought it was evident that the excess of phthisis in some trades could not be accounted for altogether by direct contagion only.

Thus far he had dealt with causes of phthisis, acting only from without; he next took into consideration the modifications of bodily constitution, rendering the person more or less liable, as the case might be, to be attacked by phthisis. The susceptibility to phthisis presented itself in various aspects; he would treat of it under the heads of Race, Inheritance, Congenital Origin, and Acquired Diathesis. Under the head of *race*, it had had shown, in reference to Peru and Bolivia, that the negroes exhibited a marked proclivity to phthisis, and next to them came the descendants of the Spaniards who took part in the conquest. Again, a race might escape phthisis in one country, and yet suffer from it in another; the liability of strangers to suffer on going to a new country was very well known, and yet sometimes the native suffered while the stranger escaped, as was the case in an epidemic of yellow fever in Mexico. Another peculiarity sometimes met with was, where in the case of

members of the same race living together, the new-comers were found to suffer excessively from a disease to which they were at least as much exposed in their own country; in such a case there must be some difference in the exciting cause in the two districts, some property in the latter place which gave it increased power over the new-comer without producing any increased risk to the native of the locality. The influence of *inheritance* was less widely distributed, but more intense than that of race; *congenital* predisposition could undoubtedly exist without any evidence of inheritance. The possibility of the *diathesis* being *acquired*, was seen in the relation observed between the development of phthisis and other diseases, *e.g.*, syphilis or the continued fevers, and also in the increased liability following upon deterioration of general health by exposure to hardships, privations, or insanitary modes of life. As to *sex*, in large towns men were more liable, in agricultural districts women were most affected.

He had now spoken of the climatic, social and personal causes of phthisis, and if it were a diathetic or developmental disease all its causes might be included in these three, but if it owned some exciting cause of the nature of a morbid poison or parasite, then all these causes would have to be regarded as predisposing causes. "Is it possible then," he went on to say, "from the examination of these three groups of causes, to draw any probable conclusion as to the nature of phthisis? I believe it to be so, and that it is a necessary step on the road to any certain knowledge of a most important subject. For such an examination will make it plain that these causes, singly or in combination, are insufficient to account for the phenomena of phthisis: that it is not, cannot be, developmental or diathetic, but must be ranked among the specific febrile deseases, and that, therefore, some micro-organism or other must be a necessary condition and not a mere accident of its presence. Unless we can find among these causes some one which is never absent, the very number and well-attested rights of the claimants, are fatal to the claims of any one of them to be regarded as the sufficient cause. Were they, each and all, always present, and in definite proportion, then indeed there would be nothing paradoxical in the uniformity of the morbid changes following their action. But that causes so diverse, so distinct as dampness of soil, exposure to a hot dry atmosphere, imperfect ventilation, an attack of pneumonia, or the being descended from a phthisical ancestor, or any other causes of the same sort should give rise singly or in combination, in all climates, under all known forms of barbarism or civilisation, to similar pathological changes, associated with a similar train of clinical symptoms, and this in spite of the manifold differences in the personal factor, this can only be accepted on the production of the most cogent proof, and in default of any simpler explanation. Indeed, the longer, the more complete the list is made under these heads, the more signal does its insufficiency become; each addition to the roll increases instead of diminishing our difficulty."

We ought to look, if we did not wish to maintain a paradox, for some constant ruling factor which could explain not only the normal but the abnormal types of the disease. The bacillus of Koch seemed to exactly fulfil these requirements. He was quite prepared to accept the doctrine "No Tubercle without Bacillus, No Bacillus without Tubercle." After referring to the old views as to the nature of tubercle and caseous matter, which he attributed in great measure to the imperfect methods of observation of necessity employed, he pointed out that there was now no difficulty in accepting the close relationship which the clinical observations of our predecessors undoubtedly established between the strumous diseases of childhood, especially those affecting the lymphatic glands, pulmonary phthisis, and acute tuberculosis. And again the anomalies in the geographical and local distribution of phthisis, and in its incidence upon different races and families and individuals could not be explained upon the developmental theory, and were in support of the micro-organism theory. "Given the bacillus," he said, "or some other micro-organism and both sets of difficulties, the geographical and the anthropological, wide apart as they appear to be, receive the self-same easy solution. The bacillus whether inside or outside the body of man, or of any other of its 'hosts' cannot thrive except certain conditions be present. The analogy of other micro-organisms (*e.g.*, that of the wool-sorters disease) and also of the higher classes of plants, proves how very slight are the changes which suffice to prevent or to favour the existence of vegetables and probably also of the lowest members of the animal kingdom; thus the distribution of many phanerogamous plants is extremely capricious. The exemption then of certain localities and of certain races from phthisis, may be, is due to the fact that the bacillus has been unable to contend with some adverse circumstance or other with which it has met, in the first case during the independent, in the second during the parasitical phase of its life."

The lecturer divided phthisis into two groups. 1. In which the onset was insidious or gradual. 2. In which it began abruptly. The latter could be again divided into (*a*) cases in which the symptoms from the very first were those of phthisis, *e.g.*, the so-called hæmorrhagic phthisis; (*b*) cases in which the disease followed sharply upon or even was continuous with some acute attack, it might be a pleurisy or pneumonia or some general fever or syphilis. The insidious form was the most typical. The period of incubation was absolutely unknown; he knew of no recorded case of the disease coming on after a single exposure, or even one of a few days only, to some source of infection; but judging from the results of inoculation experiments the period could not be a long one. Usually there was failure of strength and vigour long before any pulmonary lesion could be recognised, some form of indigestion being commonly amongst the earliest symptoms; albuminuria, too, both transient and abiding, he had known as amongst the prodromata of the lung symptoms. The night-sweats, or rather sleep-sweats, of phthisis were often most profuse in the early stages, when new growth rather than destruction of tissue was taking place; they belonged to the acute general stage of the disease, and were not merely part of the hectic due to suppuration. The sudden explosion of acute tuberculosis during the course of ordinary phthisis was found, in one instance, to be due to the bursting of a softened tubercular mass into a vein, and the consequent entry into the blood stream of a quantity of bacilli. Cases in which hæmorrhage, not due to already existing disease, led to phthisis were to be regarded as very rare.

"Thus," said Dr. Andrew, "the clinical charaeters of phthisis no less than the facts connected with its geographical distribution, and with its predisposing causes, harmonise so well with the hypothesis that some micro-organism or other is its exciting cause, and not a mere accidental attendant that it seems to me impossible to come to any other conclusion, even apart from the results of the inoculation experiments. I have dwelt on this, at what may seem to be unnecessary length, because no one who denies it, or who fails to recognise the complete change in the manner in which the problem must now be stated, has any right to claim a hearing on the question of contagion. He would be no better fitted for such a task than the blind to discourse on painting, or the deaf on music. But having stated my unreserved adhesion to

the belief that phthisis is a member of the group of specific febrile diseases, and that, therefore, like its congeners it is dependent upon some morbific germ introduced from without, am I then obliged to admit that it is propagated by direct contagion from the sick to the healthy, or even, that its transmission through indirect channels as in the case of typhoid fever or of cholera, is a matter of frequent occurrence? Most certainly not. The grounds of my disbelief in what is becoming once again the popular theory I shall lay before you in the concluding lecture. Some of them have been already incidentally mentioned, but their full force only comes out when it is seen how some of the very facts which establish conclusively the specific nature of phthisis, place it also unmistakably amongst the non-contagious members of the group to which it belongs."

Lecture III.—[Abstract.]

Comparing phthisis with malarial fever, Dr. Andrew noted many points of resemblance: both had been known from the earliest times, in both the evidence of their having been introduced into any new country by man was very inconclusive, both had prevailed in varying degrees in the same locality, an advancing in the one, and a retrograding civilisation in the other, had favoured the spread of the disease, both were widely dispersed, but phthisis extended farther north than malaria did, both varied in their characters in different parts of the world, *e.g.*, both were more acute and severe in the Tropics, both prevailed under certain unknown climatic and social conditions, both decreased in severity, and finally disappeared with increasing elevation above the sea-level; both were closely connected with wetness of soil, and both were greatly diminished, if not extirpated, by efficient drainage; both were sometimes confined locally within narrow limits, the action of the micro-organism in each was greatly modified by the personal constitution of those exposed to it; in both a bacillus had been demonstrated, cultivated, and proved by inoculation experiments to be the exciting cause of the disease; they differed in their habitat, phthisis being most prevalent in cities which afforded all but complete protection against malaria. Clinically they agreed in that recrudescence might take place after long periods of apparent health, and that in both the pyrexia was periodic.

Specific febrile diseases were very apt to be regarded as contagious without further enquiry, but it was clear that the micro-organism which was the exciting cause of the disease, stood in different cases, in very different relations to the living creature which it attacked. Sometimes, as in typhus, or small-pox, the bacillus was truly parasitical, *i.e.*, incapable of multiplying unless it met with a certain "host;" in such a case the disease was directly contagious. Sometimes the bacillus might be less completely a parasite, it might require for vigorous growth, to pass from time to time through the body of some "host." In both these cases the resulting disease was almost certain to be highly epidemic in character, sometimes causing a vast number of deaths, sometimes almost unknown, or presenting only the mildest type of disease. Scarlatina and typhoid fever were referred to in illustration of these varieties. Sometimes the micro-organism might be entirely independent, if not of any "host" whatever, at any rate of man, its sojourn in his body being unfavourable to its full development. Of course, transfusion of blood or inoculation might produce the disease, but this would in no way prove that the disease was communicable from the sick to the healty. Malarial fever probably owned such a relation as this, to some micro-organism, and, prior to the discovery of the bacillus, the known facts relating to the ætiology of phthisis led to the belief that it was more closely associated with malaria than with other forms of communicable disease. Ought the discovery of the tubercle bacillus to make us reject the former conclusion? The lecturer thought not.

The discovery of the bacillus had placed phthisis amongst the group of specific febrile diseases, a position it was quite entitled to apart from this discovery. Some of these diseases were directly communicable from the sick to the healthy; some indirectly; others were not communicable at all, except by artificial means. There was no *à priori* reason why phthisis should belong to one of these groups rather than another, or why it should not occupy some intermediate position. What then were the proofs that it was contagious? In the first place, there was an old popular superstition on the subject; and there was also the undoubted success obtained by inoculating animals, and in one celebrated instance, the human subject, with tuberculous material. Here the lecturer referred to the well-known experiments of Burdon Sanderson on the artificial production of tuberculosis with various indifferent substances, and said that, although such results ought not to be lightly put on one side, yet it was almost certain that the same experiments repeated now with fuller antiseptic precautions would not give rise to the same specific lesions; it was noteworthy that, although the disease was so readily produced in guinea-pigs by inoculation, yet they were not specially liable to it in their natural state.

Whilst then the results of direct inoculation showed that phthisis might be communicated artificially, they in no way proved that it was likely to spread through a community like scarlatina or typhoid. There was much to suggest that the bacillus of tubercle, like that of malaria, might be widely diffused, and that the risk of infection was not, perhaps, greatly increased by personal contact with the sick. The bacillus malariæ became less dangerous by reason of its stay in the human body, and looking to the capricious distribution of phthisis, and to the absence of any sufficient proof that it has been imported into any country, the same might be said of tubercle. At any rate better proof was required of its being propagated in communities by contagion. The results of feeding experiments had been called in to aid the solution of this question; the contamination of air, water, &c., by tubercle-bacilli must be as common an occurrence as in the case of scarlatina or typhoid, and might be very difficult to prevent, and yet in an epidemic of either of these, the distribution of the cases and their relation to each other almost always led to the primary source of infection at first unknown, whilst in phthisis with full knowledge of the foci from which the disease might spread in this way, we were unable to discover anything of the kind, except in some very rare instances, and on the smallest scale. Allusion was here made to a remarkable case recorded by Mr. Fleming, in which an Alsatian farmer lost a cow six years in succession from phthisis, each animal having occupied the same stall, none of the animals occupying the adjoining stalls at any time having suffered; after the stall had been thoroughly cleansed, and all the woodwork destroyed, the disease disappeared. This case Dr. Andrew regarded as pointing to local rather than personal infection, and it afforded some evidence that habits of cleanliness might play an important part in protecting a person exposed to the disease from taking it.

The largest and most important collection of observations on the communicability of phthisis among men, was that furnished by the Collective Investigation Committee of the British Medical Association. He thought, however, that there was one fault in the mode in which the investigation had been conducted which must have had considerable influence on the result.

*

This was that the Committee had asked only for affirmative cases, and consequently had not received so many answers to disprove the contagiousness of phthisis as they otherwise would have done. Out of a total of 1,078 there were 261 affirmative answers, and 165 negative. The first group in the affirmative answers was that of cases between husband and wife, from which it appears that the wife was much more likely to take the disease from the husband than the husband from the wife. In explanation of this it was pointed out that the woman in her capacity of nurse would be thrown into more close contact with the sick, and be exposed to more and greater chances of infection than her husband would be, if she were the sufferer, for he would then have to work harder to provide the necessary comforts and so would be less instead of more time in her company. Even on the diathetic theory this would suffice to explain the greater mortality among the wives. Grief, anxiety, and the various hardships and privations consequent on the illness, confinement within the house in a close ill-ventilated room would on the diathetic theory (which was perfectly true when applied as a predisposing cause only) account naturally for the excessive mortality on the female side. Indeed, the personal contagion theory failed to explain the facts under this head, for there was a most important difference between phthisis and all other diseases of this class in the matter of duration. The disease was not one of a few weeks but of months or years, and during a considerable time there might be but little change in the domestic life, so that the danger of personal contagion was fairly equal between the two for a long period, no matter which first showed symptoms of the disease. There was, however, another factor which might tell heavily against the wife, and that was syphilis; which undoubtedly when present was in the majority of cases transmitted from husband to wife. The relation of phthisis to syphilis was neither a simple nor a uniform one, he believed that the number of cases of syphilitic phthisis was very large. Sometimes an affection of the lungs closely simulating phthisis, which might be situated at the apices, and was attended by repeated and profuse hæmoptysis was really nothing more than visceral syphilis, and, though powerfully predisposing to it, was not necessarily followed by tubercular phthisis; he had known such cases to commence within a few weeks of the appearance of the primary sore, and end in complete recovery when treated as syphilis. If the nature of the illness was not recognised considerable destruction of lung tissue might take place, and, if the patient met with the bacillus, tubercular phthisis might follow, but even then syphilis would continue to be an important factor in the morbid process. After quoting an illustrative case, he said that the by no means uncommon existence of this form of disease seemed to give a more reasonable explanation of the undoubted fact that sometimes two or three wives fell victims in rapid succession to phthisis, than to believe that a contagion ordinarily so mild, as even its advocates represented it to be, should yet exhibit such portentous fitful activity. The same explanation might, perhaps, hold good also in other cases of apparent direct infection, as well as in the above. The excessive female mortality seemed to the lecturer almost inexplicable on the direct personal contagion theory, but simple and natural if attributed partly to syphilis, partly to the increased predisposition owing to the special duties of the wife and her life in-doors, and also to the fact that the constitution of the wife tended to become assimilated to that of the husband. It was to be noted that out of the 261 affirmative observations, 192 referred to married couples.

"In reviewing the 'remaining groups," said Dr. Andrew, "notice must be taken of the very small number of instances, especially of those observed between unrelated persons, which amount at most to twenty-one, and this, be it remarked, in the case of a supposed infectious disease, the contagion of which, if it exist at all, is active in the majority of its victims, for months, or even years. If cases of typhus, or of scarlet fever, retained their contagious property for an equal period, no human being could escape them. And yet upwards of one thousand observers, speaking from a collective experience of many thousand patients, can only record about a score of cases in which the disease was transmitted between persons unrelated to each other. Contagions which act directly from person to person, and which are probably parasitical in the true sense of the word, are, for the most part, extremely powerful. They do not recognise slight differences of race, or family, or climate, or subsoil water, or even of altitude above the sea-level. The only protection against them for the unseasoned, is to be found in the isolation of the sick, the speediest possible destruction of the contagion itself, and the most perfect ventilation of the sick-room. But phthisis behaves after quite a different fashion. Among persons living together in the same house, or in the same room, it picks out special strains of blood, or attacks in one family the males, in another, the females only."

In regard to these points, Dr. Andrew quoted a case from his own experience, and one mentioned by the Committee in their report; the latter was the case of a dressmaker, who died of phthisis, and whose three apprentices also all died of phthisis, contracted as was supposed, by their having taken it in turn to remain in the house with their mistress, and sleep with her, for in none of them was there any tendency to inherited phthisis. There were, however, it was pointed out, difficulties in the way of accepting the contagion theory in explanation of these cases, the contagion must have been very virulent, and yet none of the relatives of these apprentices took the disease, and, again, why should the same contagion be at one time so active as this, and at another so inert, that it was impossible to trace its operation. The number of these extraordinary facts, was not greater than might be fairly expected, as mere coincidences in the case of so common a disease as phthisis, he thought they could be more naturally explained as instances of special local infection. Dr. Bowditch had also published a case of the apparent contagiousness of phthisis, but which was in reality, much better explained on the local infection hypothesis. Only those cases could be admitted as evidence of contagion, in which the disease appeared within a moderate interval after the last exposure to the source of infection. Cases in which it must have lasted for over a year, ought not to be used as a double-barrelled argument, to prove at once the contagiousness of phthisis, and the great length of its incubation. Apparent instances of the contagiousness of ague were not known, but it was probable that they were only apparently so, and due to a recrudescence, or some such cause.

As affording a strong presumption against the direct contagion theory, he quoted the experience of the Royal Hospital for Diseases of the Chest since 1855, which, on the whole, negatived the idea of any direct contagion under the ordinary conditions of hospital residence and service. In conclusion, he summed up his arguments with respect to the ætiology of phthisis, with special reference to its contagiousness as follows:—

1. The historico-geographical argument is insufficient to prove that the present distribution of phthisis has been brought by the carriage along lines of human intercourse of a special morbific germ. Indeed, many of the facts under this head are distinctly antagonistic to any such theory.

2. Before the discovery of the bacillus, one and all of the reputed causes of phthisis were inadequate to account for its distribution, or for the anatomical and clinical characters of the disease.

3. That these causes, even those among them, which appeared to act as exciting causes, were all predisposing causes only.

4. That from the nature of these predisposing causes, their relation to each other, and the conditions under which their influence seemed to make itself felt, it was a probable inference that phthisis belonged to the group of specific febrile diseases, and that this view was held by some writers in the face of many difficulties and perplexities.

5. That the facts on which this inference was based were insufficient to prove that phthisis was personally contagious, and were, indeed, opposed to any such notion.

6. That the discovery of the bacillus proved that phthisis was a specific febrile disease, and that the question of contagion cannot now be usefully discussed without acknowledging this fact.

7. That as some specific febrile diseases are contagious, and others are not so, this property existing in very different degrees and modes, in different members of the group, the question as to the contagiousness of phthisis can only be satisfactorily answered by direct evidence of its contagiousness, and by determining its affinities with other members of the group.

8. That although phthisis may be undoubtedly produced in many ways experimentally in animals and also probably in man, there is not sufficient evidence to prove that its prevalence is materially effected by direct contagion.

9. That in many most important respects it very closely resembles ague.

10. That it is at least highly probable that the exciting cause of phthisis, like that of ague, be it the bacillus or some other micro-organism, is in no way dependent upon man for its existence, and is widely diffused irrespective of human agency.

"From these facts," said Dr. Andrew, "I may be allowed to make one short practical deduction, viz., that the prevention of phthisis, like that of ague, is to be attained by sanitary works especially of improved ventilation and drainage, and not by isolation. And that for its cure, as we should not send a case of ague to the Pontine marshes, so, too, it would be wise not to send a case of tubercular disease to any place where the death-rate from phthisis is high among the native population."

CROONIAN LECTURES ON EVOLUTION AND DISSOLUTION OF THE NERVOUS SYSTEM.

DELIVERED AT THE ROYAL COLLEGE OF PHYSICIANS,

By J. HUGHLINGS JACKSON, M.D., F.R.C.P., F.R.S.

LECTURE III.—[Abstract.]

AFTER remarking that the doctrine of evolution did not involve materialism, the lecturer began by considering the nervous system as a sensori-motor machine. His particular aim was to show that the highest centres, the physical bases of consciousness, had a sensori-motor constitution, and also that they represented impressions and movements of all parts of the organism. As he did not suppose that any one denied that the highest centres represented, however indirectly, peripheral impression, he only adduced evidence towards showing that the highest centres were representative (or rather re-representative) of movements of all parts of the body. The first evidence was supplied by epilepsy; the paroxysms in the disease were produced, he believed, by a sudden and excessive discharge beginning in some part of the highest sensory or highest motor-centres, and not by discharges beginning in parts of Ferrier's motor region (middle motor centre), nor in parts of his sensory region (middle sensory centres). A convulsion is nothing other than a sudden excessive and simultaneous development of, a contention of, very many different movements at once.

We see in a very severe epileptic fit that all the skeletal muscles are put in vigorous activity—development of movements of all parts of the body. If we take a slighter case, one of *le petit mal*, we see that the effects of the central discharge are very widely distributed over the body; there are, in such cases, effects so various, as spasm of ocular and hand muscles, pallor of the face, flow of saliva, perspiration, changes in the circulation (sometimes stopping of the heart's action, as Moxon has insisted), and arrest of respiration; there is often in, or just after, these slight fits, a discharge of fæces and urine. The existence, in some cases of *le petit mal*, of the voluminous mental states ("dreamy states"), spoken of in the last lecture (first depth of dissolution effected by an epileptic discharge), guarantees, so to speak, that the cruder effects just spoken of are owing to abnormal activity of the highest centres; the elaborate mental states mentioned, which no one will hesitate to ascribe to activity of "the organ of mind" (highest centres), never, so far as he has observed, occur in or after epileptiform seizures (discharges of middle motor centres). Then, if we take only the "warnings" of epilepsy, or rather of many different epilepsies, which "warnings" occur from, or attend, the beginning of the central discharges, we find them exceedingly various; there is giddiness, implying spasm of the ocular muscles, or of some of those of the head; there are "crude sensations" of smell, sight, hearing, and taste. Besides these we find palpitation, a peculiar sensation referred to the epigastrium, and widely referred sensations of tingling, shuddering, and shivering. Is there not here further evidence in support of the conclusion that the highest centres represent all parts of the body? Another kind of evidence from these cases is that when the severe fit is over the patient is universally paralysed. (See second lecture.)

Another, quite different, kind of evidence points to the same conclusion. Will, memory, reason and emotion are only artificially distinguished aspects of one thing, a state of consciousness. Taking them separately, and analysing their physical bases, the lectures tried to show that each implied a representation of movements of some parts of the body; that, taken together, they implied a representation of numerous different parts, if not of all parts, in the anatomical substrata of consciousness. Thus, to say that an epileptic fit is owing to a discharge beginning in some part of the highest centres (popularly "organ of mind" or "most intellectual parts of the nervous system") is equivalent to saying that it is owing to a discharge beginning in parts which form the anatomical substrata of will, memory, reason, and emotion. Epilepsy and insanity were both diseases, very different, it is true, of the "organ of mind." In an epileptic paroxysm, there is a sudden and excessive discharge of very many sensori-motor nervous arrangements of the highest centres at once; *during* such discharges consciousness ceases, and *from* them convulsion results. The mentation of the insane man occurs during slightly raised activity of sensori-motor nervous arrangements, in sequence. The following quotation shows that this was an old opinion.

"Surely the conclusion is irresistible that 'mental' symptoms from disease of the hemisphere are [on the physical side] fundamentally like hemiplegia, chorea,

and convulsions, however specially different. They must all be due to lack of, or to disorderly development of, sensori-motor processes." ("St. And. Med. Grad. Trans.," 1870.)

He then considered degrees of organisation, and having abandoned the term "most voluntary," and using in its stead the term "least automatic," pointed out that degrees from most to least organised were only another aspect of degree from most towards least automatic. Degrees of automaticity were degrees of easiness of working, implying degrees of perfection of structure. There were, he supposed, degrees of organisation from nervous arrangements whose structure was almost fixed and unalterable to nervous arrangements now making—to "nerve stuff," now being first travelled by nerve currents. He illustrated degrees of dissolution by a case of increased mental activity after fatigue, believing that the fatigue caused exhaustion of some highest, least organised, nervous arrangements, and that the increased mentation occurred during activity of the more organised, uncontrolled, nervous arrangements. (Anstie's principle.) A still more extreme case was instanced. Delirium sets in during starvation; surely it cannot be contended that from total withdrawal of food certain nervous arrangements attain greater activity? If they do, we have still to account for the negative part of the starved man's delirious condition. Does innutrition "cause" two diametrically opposite and yet co-existing states of the nervous system? Anstie's principle accounts for both.

He then spoke of those reflex actions in which the highest centres are engaged. In strong and complete reflex actions, as during what is called perception, say visual perception, all orders of centres are engaged. First, an impression on the retinal periphery, then discharge of the middle sensory, and next of the highest sensory centres—so far for the physical condition for the colour of the object. The shape of an object is, on the physical side, an affair of movements, in this case of ocular movements. After activity of the highest sensory centres, the highest motor centres were in activity, and then, by "downward currents," the middle and lowest motor centres were engaged, and the muscular periphery was reached. A vivid image, colour and shape arises during strong activities of the central links of this reflex chain (highest sensory and highest motor centres). During ideation, thinking of the object in its absence, the reflex action was incomplete and weak; only the central part of the sensori-motor process was done over again, and done weakly; thus a faint image arises.

Let us, for illustration, arbitrarily imagine there to be a centre for visual ideation and nothing else, or rather a centre for the anatomical bases of visual images only. We "store up" images of innumerable different objects, each of which has some colour and some shape; this means, on the physical side, that the centre we are supposing contains innumerable nervous arrangements, each of which represents a different retinal impression, and a different ocular movement; anatomically, these are sensori-motor nervous arrangements, physiologically, they are reflex actions During slight activities of this centre, unprovoked from the periphery, we have faint visual images; during strong activities provoked by peripheral activities, we have vivid visual images. So far for two degrees of healthy activity. Now, suppose that certain of the cells of the nervous arrangements of the visual centre, by some pathological process, become highly unstable, to a degree such as occurs in epilepsy; the consequence will be that many nervous arrangements will occasionally discharge excessively and *simultaneously*. During such a discharge there would not arise images of many objects differently coloured and shaped; but, on the contrary, there would be crude masses of vivid colour before the eyes, and there would also be a strong development of many ocular movements at once—that is to say, convulsion of the muscles of the eyeballs.

So far, as much as possible, a man has been considered as a mere machine. But consciousness attends activities of at least the highest, least automatic, parts of this machine. The doctrine, the lecturer accepts, is, (1) that states of consciousness (or, synonymously, states of mind) are utterly different from nervous states; (2) that the two things occur together—that for every mental state there is a correlative nervous state; (3) that, although the two things occur in parallelism, there is no interference of one with the other. Thus, in the case of visual perception, there is an unbroken physical circuit from sensory periphery through highest centres back to muscular periphery. The visual image, a purely mental state, occurs in parallelism with—*arises during* (not *from*)—the activities of the two highest links of this purely physical chain.

The lecturer then spoke of range of concomitance. Less consciousness attends activities of nervous arrangements, the more organised and automatic they are or have become, which means that the highest, least organised, least automatic, most imperfectly reflex centres, are the physical bases of consciousness, or most vivid consciousness; according to most authorities, the most automatic nervous arrangements have no attendant conscious state, during their activities.

The lecturer then spoke of those disorders of co-ordination which were observed when movements were attempted — started by volition, that is, speaking realistically, by discharges beginning in parts of the highest centres. All these disorders of co-ordination were, he thought, essentially cases of paralysis, that is, in the sense of loss of some *movements*—there was also an over-development of other movements of the same muscles, consequent on greater energising of *healthy* nervous arrangements: the two opposite states, (1) paralysis, that is, loss of some movements, and (2) over-development of some others, constituted the disorder of co-ordination.

The lecturer then stated his opinions as to localisation, limiting consideration to movements. For illustration, he imagined a centre for the arm and the leg. The "Universaliser" would say that every part of the centre represented the arm and the leg in the same way; the "Localiser" would say that one part of it represented the arm only, and another part the leg only—would, indeed, make two centres. The lecturer did not accept either of those views; he re-stated the opinion which he had put forward as to localisation.

"It may be said that one convolution will represent only the movements of the arm; another, only those of speech; another, only those of the leg, and so on. The facts above stated, show that this is not the plan of structure of the nervous system. Thus, to take an illustration, the external parts, x, y, and z, are each represented by units of the corpus striatum. But the plan of representation is not that some units x largely only, as x_3, others y largely only, as y_3, but that each unit contains x, y, and z—some, let us say, as x_3, y_2, z; others as x_2, y_3, z, &c. When we come to the still higher evolution of the cerebrum,[1] we can easily understand that, if the same plan be carried out, a square inch of convolution may be wanting, without palsy of the face, arm, and leg, as x, y, and z, are represented in other convolutions; and we can also easily understand that discharge of a square inch of convolution must put in excessive movement the whole region; for it contains processes representing x, y, and z, with grey matter in exact proportion to the degree

[1] At that time I arranged centres morphologically.

of complexity." ("St. Andrew's Medical Grad. Trans., 1870.")

Admitting difficulties in the way of acceptance of his hypothesis of localisation, the lecturer thought the current hypothesis did not account for all the facts. Any adequate hypothesis had to account for the following: (1) That from a destructive lesion of part of a motor centre, the paralysis was especially of the more voluntary. (2) That on a discharging lesion, the order of convulsion was the same. (3) That the progress in each (1 and 2) was in Compound Order. (4) That a part might be permanently imperfectly paralysed, and yet the whole of it might be occasionally convulsed. (5) That recovery, or some recovery, follows on permanent destructive lesions producing paralysis. (6) That a small destructive lesion of a motor centre may entail little or no paralysis, whilst a sudden and excessive discharge beginning in such part, produces (indirectly) very great convulsion. (7) That from discharges beginning in different parts of the mid-cortex, we have convulsions affecting the same regions, but their parts in different order ("isomeric seizures"). (8) That a patient, who has no paralysis before a convulsion, may have much (temporary) paralysis after it.

CLINICAL LECTURE

ON A CASE OF STONE IN THE BLADDER OF A FEMALE, AND WHAT IT LED TO.

Delivered at St. George's Hospital

By T. PICKERING PICK, F.R.C.S.,

Surgeon to the Hospital.

Gentlemen, the case to which I am about to draw your attention is that of a young woman, who was this day discharged from the Drummond Ward, cured of the infirmity for which she sought admission. The case is one of very considerable interest, and illustrates very well the difficulties one may have to contend with in what, under ordinary circumstances, may be regarded as a very simple case.

Julia W., aged 25, was admitted into St. George's Hospital under my care in May, 1883.

She gave the following account of herself:—that seven years ago she began to suffer from great pain in micturition and retention of urine. She was admitted into one of the London hospitals, where she was told that she had a stone in her bladder, and an operation was performed for its removal. She was told that the stone was of large size, but she never saw it. Since this time she has never been able to retain her water, which has constantly dribbled away, causing her the greatest misery and discomfort, and constantly excoriating the inner sides of her thighs. On two occasions an operation was performed in this hospital in order to remedy the defect, but without success, and eventually she was discharged.

In June, 1881 (five years after the first operation), she was admitted into another metropolitan hospital. I am indebted to the Surgical Registrar for the following notes of her case whilst in this hospital.

"When admitted, there was a large vesico-vaginal fistula: the urine was alkaline and bloody; there was no power of retention. On June 23rd, the edges of the fistula were pared and united with four wire sutures and beads; a gum elastic catheter was tied in the bladder, and the prone position was enjoined after the operation. On July 29th, the wires were removed; partial closure had been effected; there was considerable power of retention for a time, followed by ulceration about the fistula, and return of the incontinence. On August 8th, there was a sudden and profuse attack of hæmorrhage from the wound. The vagina was plugged. The hæmorrhage recurred from time to time without warning, and was so severe as to cause faintness. Pain in defæcation now came on, and on examination there was found to be some obstruction in the rectum, about three inches from the anus. On September 15th, an opening was discovered between the rectum and vagina; its edges were hard and raised. The fæces and urine passed from the one tube to the other. During the next four months, repeated attacks of hæmorrhage occurred from both openings, the edges of which were in a state of active ulceration.

The patient was discharged on April 29th, 1882, in *statu quo*, as not suitable for further operation, owing to general weakness, and the great tendency to ulceration and hæmorrhage following operation."

She came under my care, as stated above, in May last. I then found that she was suffering from vesico-vaginal and also recto-vaginal fistula. The vesico-vaginal fistula was of very large size, freely admitting three fingers, in fact the whole of the posterior wall of the bladder appeared to be gone. The lower wall of the urethra had also been destroyed, so that no remains of the canal persisted. The edges of the fistula were healed. The recto-vaginal fistula was of small size, large enough to admit a goose quill, situated about two inches from the anus. The tissues around were dense and cicatricial.

In spite of the unpromising nature of the case, I made an attempt to close a part of the vesico-vaginal fistula, hoping, by a series of operations, to gradually succeed in closing the whole of it. In spite of free lateral incisions, however, the amount of tension on my sutures was so great, owing to the scarcity of tissue, that they speedily gave way, and not the slightest benefit was obtained. Believing that any attempt to close the fistula would prove futile, I now had her supplied with a urinal, and sent her out of the hospital.

She was readmitted on September 19th, 1883. She complained that though the urinal was efficient in keeping her dry whilst standing and walking about, she was unable to sit down with it on, and that, when in the recumbent position, the urine leaked by the side of the apparatus and caused her bed to be constantly wet. She was in a most miserable and desponding condition, emaciated, with a wan and anxious expression, and willing to submit to any operation which would rid her of her constant trouble and annoyance.

Accordingly, on October the 18th, the patient having been placed under the influence of ether, and in the lithotomy position, I dissected up a circular belt of mucous membrane from the inner surface of the labia minora, just within the orifice of the vagina. By this means I laid bare a surface, an inch in depth, completely round the vagina. I then introduced a curved pewter tube through the recto-vaginal fistula, from the vagina, so that the end protruded out of the anal orifice. The raw surfaces were now brought together with three deep quilled sutures, and five superficial silver wire sutures, so that the orifice of the vagina was completely closed.

After the operation she suffered considerable pain, but otherwise did well. The quilled sutures were cut on the fourth day, and removed on the sixth. On October 30th (the twelfth day after the operation), she was placed under the influence of ether, and the silver sutures were removed. The tube was also withdrawn from the rectum. The whole of the wound was firmly united.

Upon visiting the patient next day, she exclaimed, with tears in her eyes, "Oh! I am so much obliged to you, Sir! I slept all last night without wetting my

bed, an event which has not happened to me for the last seven years."

I determined to keep the patient under observation for some time, and directed that the vagina and bladder should be syringed out daily by a catheter introduced through the recto-vaginal opening with a weak solution of nitric acid (℥ ij ad. ℥ j). On November 3rd, she got up and walked about the ward, and was able to retain her water. In fact, she states that she can retain it "as long as she likes." I made an examination on November 13th, and found that there was no deposit of phosphates on the vaginal mucous surface. I therefore gave orders that she should be instructed to pass the catheter for herself, and this having been done, she was discharged on December 1st. My clinical clerk makes the following note in his case-book on the day of her discharge :—"Her countenance shows a marked change from her previous condition. She now looks happy and bright, and is gaining flesh rapidly."

And such, indeed, was the fact. I never remember to have seen such a notable change in the appearance of any patient, from the anxious, careworn, and piteous expression which she presented on admission, to the bright and happy smile which illumined her countenance when she wished us "good-bye."

I ought, perhaps, to have mentioned, that for the last twelve months she has not menstruated ; but no doubt with her improved condition this flux will return, and there seems no reason to doubt that it will find its way through the fistulous opening as readily as the urine, and that she will menstruate through the rectum.

Such, then, gentlemen, is the history of our case, and there are several points of interest in connection with it to which I shall briefly draw your attention. And the first point to which I would allude, is the infrequency with which we meet with stone in the bladder of the female. Of course, I do not allude to those cases of phosphatic concretion formed around some foreign body introduced from without, which, unhappily, are by no means uncommon in the bladders of young females ; but to calculi, either lithic acid or oxalic acid, originally formed in the kidney and passed down the ureter into the bladder, or to true phosphatic calculi, which appear to originate primarily in the bladder. Is this rarity due to the less frequent formation of stone in the female? or is it due to the fact that, when present, on account of the absence of any prostate gland, the shortness of the urethra and its dilatability, they are unconsciously passed and, therefore, do not come under our notice? I have no doubt that stone in the female is much more common than is generally supposed, and that the calculus is passed *per urethram* without even the patient herself being aware of the fact. That even large stones may be passed without any effort or discomfort to the woman herself is evident from such a fact as this—that a stone, as large as the one I show you, could be passed by a woman whilst she was engaged in dressing her mistress's hair, yet such was the fact.[1]

It is probable, however, that the lithic acid calculus is not so common in the female as in the male, on account of the higher living and the greater amount of stimulant to which the latter is very often accustomed. We know that gout, with which the lithic acid diathesis is intimately associated, is more common in the male than in the female.

Another point in connection with this case to which I wish to draw your attention, is the best method of dealing with stone in the bladder of the female. We may remove them either by lithectasy, lithotomy, or lithotrity. By *lithectasy*, or dilatation of the urethra, which may be either rapid or gradual. I hold a very strong opinion that the method by rapid dilatation is the only one which should be employed for the removal of *small* stones. When we consider the ease with which we can dilate the female urethra, so as to introduce the finger into the bladder for purposes of exploration, and the perfect harmlessness of the proceeding, we shall feel that we have in this way a safe method of removing small stones—say, of not more than an inch in diameter. When the stone is larger than this, there is a probability of lacerating the mucous membrane and unduly stretching the muscular coat of the urethra, and thus setting up permanent incontinence of urine.

The plan of operating by gradual dilatation, by means of sponge tents, ought not, I think, to be practised, as likely to lead to incontinence. Mr. Bryant, in a paper read before the Medico-Chirurgical Society in 1864, gives a tabulated statement of 28 cases of stone in the female bladder in which the stone was removed by dilatation. In four of these cases only was the operation followed by incontinence ; and, curiously enough, these four cases had all been treated by *gradual* dilatation. Such a fact as this is sufficient, to my mind, to condemn this mode of operating.

When the stone is of greater size than one inch in diameter, I then believe that vaginal lithotomy is the best operation. Some surgeons have proposed to remove the stone by slitting up the urethra ; but it has been found that in about one-half of the cases in which this has been done, permanent incontinence has been the result, and I, therefore, only mention the operation to condemn it. We have Sir Henry Thompson's great authority for preferring vaginal lithotomy to lithotrity when the stone is *large*, and when it is small, as we have seen, we have a better method than either in urethral dilatation. Sir Henry Thompson says, with regard to lithotrity, "The bladder soon becomes empty, and the manipulation and removal of large, sharp, and angular fragments in that condition I consider a very hazardous proceeding, and one which probably involves more damage to the urethra, to say nothing of the bladder, than the removal of a good-sized stone entire." With this opinion I cordially agree. Of late years some surgeons have recommended that, after crushing, the stone should be removed by Clover's or Bigelow's evacuating bottle ; but this is not always applicable to the female bladder. The essence of Bigelow's method is to keep the bladder full during evacuation of the fragments ; and so particular is Bigelow on this point that he recommends that an elastic ring should be placed round the penis to prevent any water escaping by the side of the catheter. This, of course, cannot be done in the female, and it is found that the water escapes almost as soon as it is injected. In the patient from whom I removed this large phosphatic concretion, after crushing, I attempted to evacuate with Bigelow's bottle, but had to desist on this account.

It is true that vaginal lithotomy may be followed by vesico-vaginal fistula, as in the case just narrated, and that is the great objection to the operation. On referring to the literature of the subject, I cannot find that this is of common occurrence, nor do I remember any instance in which the accident has happened in the practice of this hospital. There is one word of caution, in performing this operation, which I may give you, and that is, that the incision through the vesico-vaginal septum should be free enough to allow of the stone being easily extracted. If any force has to be applied in pulling the calculus through the opening, the edges of the incision will be torn and bruised, and consequently some sloughing may take place, with want of union of the wound, and as a result a vesico-vaginal fistula.

A third point of interest in our patient's case arises

[1] The stone exhibited was 1⅛ inch in its longest diameter, and ⅞ of an inch in its shortest. Its longest circumference was 3¾ inches, and its shortest 2½ inches.

out of these last remarks and that is, the reason of the formation of the fistula. Why did the wound not heal as it ordinarily does? I think we have the answer to this in the behaviour of the wound after the several plastic operations which were performed. It will be remembered that, after one of the operations, it is recorded that the wound took on an ulcerative action, accompanied by severe hæmorrhage, and there can be little doubt that the failure of union in the first instance was due to the same cause. The patient's constitution was naturally unsound, though, as far as we could learn, there was no syphilitic or specific taint; and owing to this general weakness no healthy union took place. Each succeeding operation was attended by a similar ulceration, and so the gap widened until it assumed the size which it was when she came under my care.

The cause of the formation of the recto-vaginal fistula is not so clear. I am inclined to think that owing to this same general weakness, an abscess formed in the recto-vaginal septum, and this was the cause of the pain in defæcation complained of, and the obstruction in the rectum which was noted at one period of the case. This abscess subsequently burst into the two tubes, and thus the fistula was established. This hypothesis seems the more probable from the fact that, when the opening was first discovered, its edges were noted to be hard and raised. The formation of this fistula, which, no doubt, was regarded as a serious complication, really appears to be the turning point in the case, as it opened up the way for us to divert the urine in the manner described.

One other point in connection with this case requires consideration, and that is, whether I did right in performing this operation. It seemed to me to be impossible to close the large opening which existed, and the only other proceeding which suggested itself to my mind was inapplicable in this case, and that was to sew the lower margin of the fistula to the posterior wall of the vagina. She would then have menstruated through her bladder and, of course, would have been incapable of bearing children, but, no doubt, would have been able to fulfil the duties of married life. This plan has been suggested as a remedy in these cases of extensive destruction of the posterior wall of the bladder, but was not applicable in our patient's case, because there was no urethra, and, therefore, there would have been no power of retaining the urine. Besides it would not have dealt with the recto-vaginal fistula. Of course, the proceeding condemns the patient to a life of celibacy, and this we had to explain to her before commencing the operation; so great, however, had been her sufferings during seven years of incontinence of urine, that she willingly consented to anything we might suggest which would rid her of her infirmity.

ON THE NATURAL MINERAL WATERS OF LEAMINGTON.

By R. EARDLEY WILMOT, M.B. Lond., &c.

The influence of fashion over therapeutics is a thrice-told tale, and has been dwelt upon by many authors, and from almost every point of view from which comment and illustration has seemed possible. In no respect, it seems to me, can more decided confirmation be found of this truth, well worn yet ever new as it is, than in the rise and fall of the popularity and use as health-resorts of our English mineral watering-places. I have no intention, in this paper, to dwell upon the virtues and desirability of our English mineral Spas in general, or, indeed, to give more than a passing glance at any besides that one (the Royal Leamington Spa, as it delighted to call itself fifty years ago), in which my lot is at present cast. Suffice it to say, that the present day has witnessed a most remarkable revival of the favour and prosperity now again rejoiced in by nearly every one of those national health-resorts which depend on their mineral springs for their therapeutic reputation. Bath, Buxton, Harrogate, even, to a less extent, Tunbridge Wells, Droitwich, and minor Spas, are astonished at their own new-found popularity, and are delightedly sunning themselves in the warmth of restored confidence. In no one of these favoured spots has any fresh health-giving influence been developed, it is simply that the wheel of fortune has again raised them from the depths, and caused a new lustre to shine over those curative virtues, which their medicinal virtues have always undoubtedly possessed.

Leamington alone has been left out in this revival; by some strange chance this Spa, the variety and peculiarity of whose mineral waters should make it second, as a place of invalid resort, to no locality in Great Britain, remains still comparatively unsought and unappreciated. Now there is no reason, as I hope to show, why this state of things should become permanent.

The Leamington waters are as abundant and as curative in their influence as they were in the days, not half a century ago, when the sick flocked there in such numbers for relief that the place sprang, with a mushroom-like rapidity, from "a cluster of insignificant thatched houses," as a writer of the day puts it, "to such a fame and magnitude as to rank among the most celebrated watering-places of the country." Nor was it any question of mere fancy and fashion. Vast numbers of remarkable and well-authenticated cures were undoubtedly performed and are still on record, and we cannot doubt that the Spa as well deserved its well-grounded reputation as any other mineral watering-place in Great Britain or in Europe. No article on the subject of the Leamington waters could be complete without mention of the late Dr. Jephson, the *genius loci* of the place, the remarkable man under whose strong individuality the unprecedented growth of the Spa was attained. We doubt if in the annals of medicine any more extraordinary achievement is on record than this, the development of a humble Midland village into a large and populous town by sheer force of personal energy and talent, in insisting upon the virtues of a mineral water which had at most, before his day, but a narrow and local repute. Yet this great man was himself the first always to aver that he owed his success not solely, or, indeed, principally, to his own exertions, untiring as they were, but to the actual beneficial effects of the mineral water, upon whose fame his own advancement had been based. The decline of the Leamington Spa, as a health-resort, since the days of exceptional favour and prosperity which I have indicated, has been due to a variety of local causes, but not in any degree to an alteration in the chemical character or capacity of the springs. Of these local causes none, except the supineness of the Corporation authorities, and their blindness to their own best interests, exist at the present day. There is no reason, social, physical, or scientific, why the Royal Leamington Spa should not at once be restored to its old position of public favour and resort. The climate is as equable as ever, the town as well built, well drained, and well cared for; the surrounding scenery as choice, and the means of public amusement and relaxation even more numerous than in the days of its fair fame. The waters gush as ever from the parent springs, and the diseases to which they have an undoubted and well-proven therapeutical affinity are as common and as grievous as of old. We want simply the sun of fashion to shine upon us, and we

anticipate with some confidence the withdrawal of those clouds of obscurity and neglect which have gathered round us.

What, then, let me show, in the first place, is the composition, as shown by analysis, of the Leamington Spa water; and what, in the second place, are those forms of disease in which a course of these waters may reasonably be advised? According to Loudoun, who wrote in 1831, the author to whom I have before referred, there were, at that date, no fewer than *eleven* medicinal springs in actual use. These varied considerably in chemical constitution, and it was, in fact, upon this "number, variety, and abundance" of the mineral springs "uniting in a single spot, waters similar to those of Harrogate, Tunbridge, and Cheltenham," that the reputation of the Spa was based. It would appear, indeed, that in the basin or depression in which old Leamington was placed, a stratum, or various strata, of saliferous, chalybeate and sulphurous character underlay the surface, and that, by this means, the waters of the springs, to an extent corresponding with the depth from which they emanated, became medicinally impregnated. These eleven springs were classified by our author under three main heads—the saline, the sulphuretted, and the chalybeate. It could never be maintained, however, that the sulphuretted and ferruginous springs, though actually existing, could claim such strength of impregnation, as to compete successfully with the waters of other Spas (such as Harrogate and Tunbridge), in which the sulphur and iron are contained in much larger, and more truly medicinal, proportions. It was the saline springs to which, of our local waters, the chief fame attached in the past; and it is upon these that we must chiefly depend for our good repute in the future. The saline springs at present in use are four in number, and, though differing somewhat in the amount of solid ingredients which they severally contain, they have practically such an identity of composition, that but slight direction is necessary as to which spring, in any particular case, should be made use of. The waters, as drawn from the pump, are cold, sparkling and transparent, containing a considerable quantity of carbonic acid gas in solution, which escapes, with a slight fizzing noise, while the glass is held in the hand.

On analysis they yield, according to Braun (1875; translation, edited by Hermann Weber) per imperial pint as follows:—

Sulphate of Soda.	Chloride of Sodium.	Chloride of Calcium.	Chloride of Magnesium.
28 to 40 grains.	40 to 60 grains.	20 grains.	3 to 12 grains.

About one grain of iron, with traces of bromine and iodine, and two to three cubic inches of carbonic acid. The amount of each salt varies according to the spring from which the sample is taken. The taste varies also, from the same cause. All the springs contain a trace of sulphuretted hydrogen, but scarcely in medicinal or curative dose.

This author (Braun) observes, "We can see no reason why Leamington should not again become a much frequented and useful watering-place, the more so as in many instances it may be resorted to in early autumn, or even winter, on account of its great mildness of climate compared with Continental Spas." It would seem, indeed, that mineral waters, inexhaustible in quantity, and having such a decided saline composition as that above indicated, should not be allowed to fall into disuse and non-repute. There are most undoubtedly a large class of diseases for the relief of which, on account of their mixed saline and aperient effect (due to the sulphate of soda which they are shown to contain), they must have a valuable influence. Such diseases are dyspepsia, hepatic, portal or uterine congestions and their results, and many diseases consequent upon sedentary employment or too-generous diet. It was, indeed, to the *bon vivans* that Jephson, in the old days, more especially addressed himself, and among this class of sufferers that he obtained some of his most remarkable successes. And there can be no doubt that now, in the present day, those forms of dyspepsia and congestive conditions of internal organs, induced by alcoholism or other intemperance in eating or drinking, late hours, or the general atonic condition which follows, as a Nemesis, the enjoyment (*à la mode*) of the London season, might be distinctly and rapidly benefited by a course of such waters as these. That, this, indeed, is the fact, the experience of all on the spot, who have combated such conditions by these means, will amply testify. Other of the saline ingredients tend more especially to the production of diuresis, and hence to the relief of chronic gouty, and rheumatic affections. Some remarkable cures of sciatica and allied complaints are on recent, as well as ancient, record. It is also a matter of common observation here, how materially the influence of chalybeate remedies in anæmia, chlorosis, &c., is aided by the exhibition, at the same time, of the saline Leamington waters. This is not due to the fractional quantity of iron which the waters themselves contain, but rather to the action of the salines, in aiding assimilation and absorption, and producing regularity of evacuation, in counter-action to the astringent effects of the ferruginous preparations.

The sulphuretted hydrogen, iodine, and bromine contained in these waters, though appreciable in quantity, are yet in such small proportion, that, in my opinion, their medicinal effects may be practically disregarded.

But there is another ingredient of these waters, on the influence and success of which, as a curative agent, I should be disposed to lay much greater stress now than was done either by authors or physicians in the past. In the *Chloride of Calcium*, which is contained in the Leamington waters, in the large proportion of gr. 20 to the pint, I believe we have a most valuable remedy. And since this proportion of the salt to the water is greater than that in which it is contained in any other mineral water of England, while the salts with which it is combined in such useful ratio, are such as to aid its action, I believe, that it is on the therapeutic utility of this chloride of calcium, that much of the future prestige of the Leamington Spa will depend. In this opinion I am supported by that of other physicians of this place, and believe, in common with them, that an effort should now be made to promote the use of our waters on this as well as on other accounts. The action of calcium chloride upon the glandular system, as an absorbent of morbid products and deposits, is well known, and the mineral waters of Leamington have always enjoyed a certain reputation for this action. They are, indeed, in constant use at the present day in this town, and with the best results, for the purpose above indicated. Bronchocele; tabes mesenterica; strumous, lymphatic, or other glandular enlargements, in any situation, external or internal; chronically enlarged tonsils; scrofulous diseases of joints have all been severally benefited, in many well-noted cases, by the use of the Leamington Spa waters. In certain stages of phthisis, and forms of tubercular and other wasting diseases of childhood, the chloride of calcium has been believed, with apparently good reason, to exert a beneficial and controlling influence. Here, again, these waters, containing so large a portion of the salt, would be indicated. The course of chorea has been supposed to be favourably

influenced and shortened by the action of this agent, and though on this point further evidence may be desirable, yet the waters, combined with other tonic and hygienic treatment, might seem to be suggested. Sarcinous vomiting has been so often successfully treated by chloride of calcium, that the remedy scarcely needs additional advocacy in this direction. It is on record, by many observers, that uterine fibroid tumours have their growth checked, and their degeneration accelerated, by the exhibition of the calcium chloride. Such cases have been undoubtedly observed here, under the use of the mineral waters.

Here, then, we have a numerous group of diseases, for all of which our medicinal springs stand in the proved relation of curative agents, on account of the large proportion contained in them of the chloride of calcium. There are other groups of common diseases, in which, as I have endeavoured to show, the other saline ingredients exert a most markedly beneficial influence. And the rare state of combination in which these salts exist in the spring water is such, I firmly believe, as to aid their action in the greater part of the diseased conditions alluded to. I would not, of course, claim for these waters any *specific* or *unintelligible* virtue, but at least I would say, that they are superior to many other waters now in more common use. And I would submit that a case has been made out for the reintroduction of this Spa to public favour and confidence. It can hardly be that waters which were so widely and signally beneficial fifty years ago are useless now. It is merely that the wave of fashion has not yet rolled back in our direction.

As to the manner in which the waters should be taken, experience has shown that the dose and the mode, the frequency and duration of their administration, and the spring which should be selected, must vary to a great extent with the case under treatment. No general rules can be laid down, and no special cases described or enumerated, in a paper of the dimensions of my present one.

As to the time of year at which these waters may be recommended, it may be safely said that they may be taken internally, in suitable cases, at any season of the year. From May till October is, however, the season most adapted for their exhibition. The pump-room and bath accommodation are ample, and now that the Corporation are again moving in the matter, there can be little doubt that appliances for the employment of all modern forms of Balneotherapy will be supplied in perfection. That this has scarcely, of late years, been the case, has been due to the coldness with which our Spa, in common with others, was for many years regarded by the public. Now, that the revival of the mineral Spas of England is an accomplished and welcome fact, we hope that the Royal Spa of Leamington, as deserving, I believe, as any in this country, will again rejoice in public favour and support.

Active Interference in the Management of Abortion.—A recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie* contains an article by Dr. H. Spöndly, of Zürich, on the above subject. The interference which he recommends is simply that, in every case of abortion, the medical attendant should take care that nothing is left in the uterus, should completely remove placenta and membranes; and that in every case of threatened abortion, where the hæmorrhage is profuse, and does not yield to treatment, the uterus should be emptied as soon as possible. The expulsion of the placenta should not be left to nature. In this recommendation there is of course nothing novel, nor has Dr. Spöndly any new instrument, or method of effecting the desired end. The main importance and interest of the paper is in the fact, that the author gives a series of 53 cases in which he acted on the principles which he lays down, and with uniformly good results.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

SEAMEN'S HOSPITAL, GREENWICH.

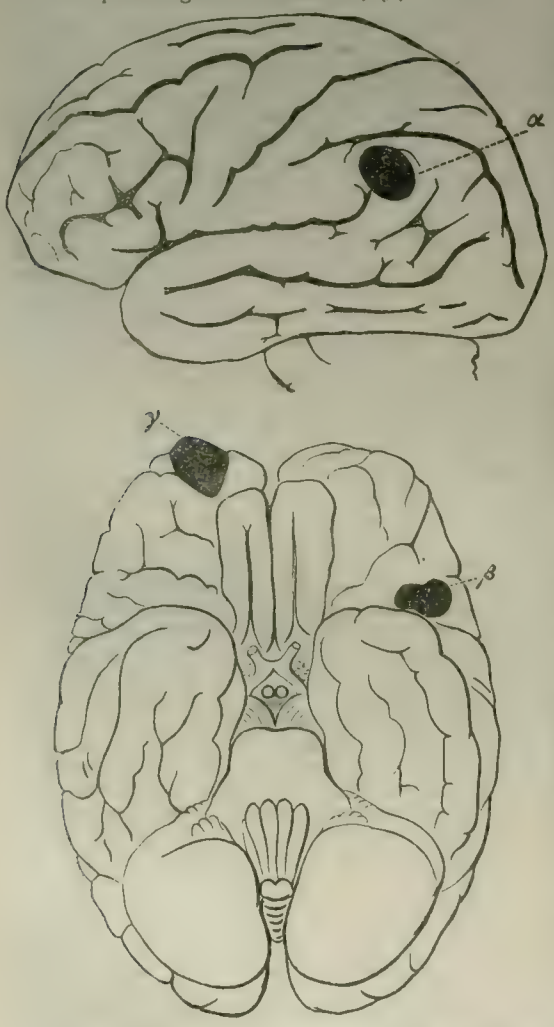
SYPHILIS—APHASIA—GUMMATA IN THE CEREBRAL CORTEX.

By JOHN CURNOW, M.D., F.R.C.P.,
Physician to the Seamen's and King's College Hospitals.

J. L., an American, aged 32 years, was admitted into the Seamen's Hospital on November 30th, 1881. He gave a clear history of primary syphilis five years previously, followed by a slight secondary rash and sore throat. Two weeks previously he had an abscess on the left side of the face, when a small piece of the lower jaw exfoliated. He had suffered from three attacks of gonorrhœa, and frequently from what he called rheumatism. Otherwise his general health had been good, and he had suffered from no acute illness.

When admitted, although quite conscious, he could scarcely utter a word, and was evidently suffering from severe pain in the head. He vomited frequently, his tongue was furred, and his bowels were constipated. His pulse, respirations, and temperature were normal, and there was no albumen in the urine. His heart and lung-sounds were quite normal; there was no paralysis of his face or limbs. Some time afterwards he gave this history of his attack—"I was working on board the ship, which was then in the docks, and suddenly found, on one of my mates speaking to me, that I could not answer him. I had a severe headache, but no fit. It came on all at once. I was not paralysed." This occurred on the morning previous to his admission. He was at once ordered a purge of calomel and jalap, his bowels acted freely, and the sickness soon passed off, although the headache remained. He took 30 grains of iodide of potassium every four hours for some days, and then three times daily until December 14th. His aphasia gradually disappeared, and on December 10th he could name things readily, count up to ten, although he hesitated over the number five, and write plainly and without a mistake when asked to do so. He could read aloud and spent some time over a book, but after he had read two consecutive pages, had no recollection of what was on the first page. These facts were clearly made out by repeated observations. On the 14th, he complained greatly of pain in the head, and limited its seat by drawing a circle over the left temporal region from a little behind, and on a level with the angular process of the frontal bone, to just above and as far back as the external ear. He could now read for some time without forgetting the context. On this day, perchloride of mercury, in $\frac{1}{16}$-grain doses, and 10 grains of iodide of potassium were substituted for the larger doses of iodide, and a blister was applied over the seat of pain. On the 18th, he said that the pain was much less, but that he felt a numbness, as if he had been struck with something heavy like a sand-bag. His aphasia had almost completely disappeared, and only an occasional hesitation, like a stammer, could now be detected. On the 24th, the pain was quite gone, he could read and speak quite well, and was doing some of the lighter work in the ward. He remained in good health until January 14th, when he was again attacked with headache and vomiting. In spite of treatment (including blisters and a seton) these symptoms continued almost without intermission, and towards the end of January he

gradually became unconscious. On the 30th he passed his urine and fæces beneath him and gradually getting weaker, without regaining consciousness, or exhibiting any fresh symptoms, he died on February 4th. Permission could only be obtained to examine the brain. On removing the skull-cap, the internal surfaces of both parietal bones were slightly roughened and diseased, especially the left parietal eminence, and the posterior wall of the pituitary fossa was also carious. The meninges were somewhat congested, and adherent over the tumours described below, but there was no diffuse meningitis. Three tumours were found on examining the cortex; (*a*) one, the size of half-a-crown superficially in the left supra-marginal convolution; (*β*) a second, the



size of a filbert on the orbital surface of the left frontal lobe just in front of, but not invading, the fissure of Sylvius; and (*γ*) a third, superficially as large as a shilling, on the orbital surface of the right frontal lobe, outside and in front of the triradiate sulcus. The position of these tumours is shown in the annexed woodcuts. The rest of the cortex and the islands of Reil were quite healthy. The middle cerebral arteries were quite pervious throughout. On careful examination it was found that the tumours involved the grey cortex only, and there was no softening, redness, or other indication of a diseased condition of the white fibres beneath. In fact, the tumours broke down easily, and their deeper soft parts could be washed away by a stream of water, so that their extent could be readily ascertained. The interior of the brain was quite normal. A microscopic examination of the tumours showed the usual features of syphilitic gummata.

It is important to notice the great accuracy with which the headache corresponded to the site of the principal lesion, and the failure of anti-syphilitic treatment in the second attack, although in the first attack the recovery of the patient during its exhibition was very rapid, and the daily progress most marked.

The case also presents some interesting features in relation to the localisation of the functions of the brain. In the earlier attack aphasia was the only functional disturbance indicating a central lesion; in the later attack the patient gradually became weaker and died comatose, without any recurrence of the aphasia. Broca's convolution—the posterior extremity of the third left frontal—was undoubtedly healthy, and had not undergone any compression, nor did the membranes over it show any sign of former disease. The tumours (*β* and *γ*) on the inferior surface of the brain involved no cranial nerve, and, as we learn from the experiments of Ferrier that the results of stimulation or removal of the orbital gyri are negative, we may with tolerable certainty leave them out of consideration.

The lesion in the supra-marginal convolution (lobule du pli courbe), is more important, for this corresponds most closely with Ferrier's visual centre, and as the tumour was limited very definitely to this lobule, and did not extend into either the temporo-sphenoidal lobe, the ascending parietal convolution, or the postero-parietal lobule, the absence of any interference with hearing, or with the due understanding of ideas conveyed by sound, or of any disturbance of the motor functions of the hand or foot, may be readily explained. The aphasia was peculiar in the fact, that after the patient had recovered his memory of words and the proper use of them, as well as his power of calculating and of writing, he could not remember what he had been reading just previously, and as he still went on with his reading, and turned over the leaves just as if he appreciated its meaning, it was obvious that he attached no real signification to the words which he saw and uttered.

Cases in which patients preserve their intelligence and their power of expressing ideas by writing, whilst incapable of reading or of grasping the signification of the words the letters form, have been described by M. Magnan and other French observers as *cécité des mots*, and an interesting example, in which the supra-marginal convolution was involved in a sarcomatous growth, was communicated to the Société de Biologie, in June, 1880, by Dr. Déjérine.[1] In these cases the centre for the formation of the words which are applied to our mental images as formulæ or names, may be intact. This formulation seems to be the special function of Broca's convolution.

But for forming a complex mental image of an object, various centres such as sight, touch, smell, hearing and taste are all necessary, and if the visual or other centre be impaired there will be, by so much, a relative deficiency in the formation of the mental image itself to which the name is applied. Between seeing an object and giving utterance to its name, a complex nervous mechanism must intervene, apparently necessitating connections (*a*) between the retina and the corpora quadrigemina; (*β*) between these bodies and the cortical visual centre; (*γ*) between this and Broca's convolution; (*δ*) thence to the nerve-nuclei in the medulla oblongata; and, lastly, through their special nerves to the muscles, articulation. A deficiency in the vividness of the mental image might afford a possible reason why the meaning of the word is sometimes lost although

[1] "De la Cécité et de la Surdité des Mots dans l'Aphasie," par Mdlle. Skwortzoff. A most able thesis, kindly lent to me by my colleague, Prof. Ferrier.

the letters which make it up can be spelt correctly, and why a person may read on and on forgetting the significance of the preceding passage or sentence. The mental image impressed upon the visual centre is not sufficiently powerful to recall the memory of a former presence or to be reproduced, and so a break in adapting the new image to the meaning of the words he reads may occur on the receptive side of his cerebral mechanism.

Medical Times and Gazette.

SATURDAY, APRIL 12, 1884.

THE most noteworthy feature of the debate on the third reading of the Government Medical Bill was the speech in which Lord Camperdown bestowed his benison upon the measure ere it left the Upper House. We cannot flatter the noble Earl by a belief that his approval of the Bill will in any appreciable degree facilitate or hasten its progress in the House of Commons; for his Lordship highly approved of the Bill last year, and yet it never got beyond the threshold of the Lower House. Still, as Lord Camperdown is a man of marked ability and power, and was chairman of the Royal Commission on the Medical Acts, he speaks on the subjects of Medical Reform with an authority and weight to which very few laymen can have any claim. His support has, therefore, undoubtedly been of considerable value to Lord Carlingford; and it is of interest and importance to find that he still very decidedly holds the opinion that the Bill ought not to add to the already bewilderingly numerous medical titles granted in the United Kingdom by authorising the new Board of Examination to create a new title. He thinks that Lord Carlingford has gone to the furthest extent of conciliation in dealing with the claims of the Medical Corporations; but, on the whole, he approves the measure, and hopes the Government will press it forward as much as possible in the House of Commons. It is still uncertain what kind and degree of opposition the measure will meet with in that House. But so far as time for consideration there is of importance, it has a somewhat better chance of success now than it had last year, as it leaves the Upper House at the commencement instead of at the very end of April.

ON Monday last, that having been the first Monday after Palm Sunday, the Fellows of the Royal College of Physicians, in accordance with their laws, met in College to elect a President. Other business may be and is transacted at this fixed assembly, but on no other day in the year and at no other meeting can the election of a President take place. The occasion is always, therefore, one of special interest and importance, and rarely has this been more markedly shown than it was this year. The business of the College has of late years steadily increased, till the demands on the time of the President have become extremely onerous; and it had for some time been an open secret that the retiring President, Sir William Jenner, would not feel able to accept the honour of re-election unless the College could find a method of relieving their President from the burden of some of his routine and less important duties. According to the present by-laws of the College, "in all cases of the unavoidable absence of the President, or of his inability to act, he shall appoint a Fellow of not less than ten years' standing, who shall act as his *vicarius*"; and this provision was quite sufficient while the duties of the President were so light that even a very busy man could fulfil them without any serious sacrifice or inconvenience. But that is far from being the case now, and as the expediency and desirability of giving the President relief has become more and more apparent, it has been more and more felt that the method of relief prescribed by the existing by-laws, is inadequate and cumbersome. It is inconvenient and not dignified for a President to have to search, on emergencies, for a fitting Fellow of the College who can and will oblige him by acting as his substitute; and on Monday the Fellows met with the desire and intention to find a ready and expedient mode of lightening the burdens of the Presidency, and of, if possible, retaining for the College the services of the retiring President.

BOTH intentions were happily and fully carried out. In a College of more than 100 Fellows, Sir William Jenner was, for the third time, re-elected President, by what was practically a unanimous vote, no other Fellow except Sir William Gull obtaining more than a single vote. And the Fellows passed, for the first time, a resolution to the effect that "two Vice-Presidents shall be added to the officers of the College," and appointed a Committee to draw up a scheme of regulations for the appointment, position, and duties of the new officials. The College may well be heartily congratulated on these results. There can be no question that their President ought to be provided, in a direct and dignified way, with officers whose duty it shall be to relieve him, when he wishes it, of some of the routine duties and the least important labours of his office; and it would have been a deplorable mistake had any hesitation on the part of the Fellows, to afford the needed assistance, deprived the College, in these days of impending medical legislation and changes, of the guidance and counsel, as President, of a man who has acquired such influence with, and enjoys in such an exceptional degree, as Sir William Jenner does, the trust and confidence of, all classes of society.

BEFORE proceeding to the formal business on the Agenda paper of the day, the President proposed, in brief and very feeling terms, addresses of condolence, on the part of the College, with Her Majesty the Queen, and the Duchess of Albany, on the grievous loss they have sustained in the death of His Royal Highness the Duke of Albany. In moving those addresses, Sir William Jenner dwelt especially on the regard the late Duke felt for, and the interest he took in, all that particularly concerned the profession. Several Fellows of the College had had opportunity, he said, of attending the Duke of Albany, and he never forgot their services. During his prolonged delicacy

of health, and his many illnesses, he must have frequently been tempted, if not urged, to avail himself of the services of some of the loud-voiced and vain-glorious boasters among irregular practitioners; but his intelligent trust in the scientific practitioners of our Art had never failed, and confidence in them had wavered never. In this, as in many other respects, he had set a brilliant example to the educated classes of society. The proposed addresses were, of course, unanimously agreed to.

An Amended Report was presented by the Committee, appointed by the College to draw up suggestions regarding the new edition of the Pharmacopœia. The Committee recommended the addition of thirty-three substances; the omission of three (Digitalinum, Dulcamara, and Enema Tabaci); alterations in the composition of a few others; and changes in the recommended doses of some eight preparations. The Committee further suggested that Calamine and the Spiritus Ætheris Sulphurici Compositus (Hoffman's Anodyne) be restored to the Pharmacopœia. After some slight discussion, and the rejection of a proposal to omit, from the list of recommended additions, the Iodide of Ammonium, the Hydrochlorate of Apomorphia, Gelsemium, and Hyoscyamin, the Report was adopted, and directed to be transmitted to the Pharmacopœia Committee of the General Medical Council.

Among other matters that came before the College, it may be mentioned that it has been decided that in future the Harveian Oration shall be given on St. Luke's day (October 18th), the day on which it used to be delivered, and on which Harvey's remains were consigned to their new resting place. The College was asked, and after due consideration agreed, to pass for the first time a by-law enacting for this year, that the election of Members to the Fellowship of the College shall take place at a meeting to be held on the last Thursday in May instead of on the last Thursday in April, as is required by the existing by-law on the subject. No Member can be elected to the Fellowship unless he has been previously nominated by the Council; and as, while at ordinary meetings of the Council five members form a quorum, at those meetings at which members of the College are selected for nomination to the Fellowship, the quorum must consist of at least fifteen members of the Council, it is not difficult to imagine a failure, now and then, to form the necessary quorum. Such a failure has certainly been, to say the least, very rare; but its actual occurrence has been the cause of the enactment of a new by-law *pro hâc vice*.

At the Medical Society, on Monday last, Dr. Joseph Coats, of Glasgow, read an interesting and suggestive paper on "Compensatory Hypertrophy." After defining the term, and drawing the distinction between it and hyperplasia, he proceeded to examine the organs of the body individually, and pointed out how and under what circumstances they took on this compensatory hypertrophy. In the heart we are all acquainted with the process, but in the liver, and in the lung, and intestine, for instance, we are perhaps less familiar. That it exists, however, Dr. Coats pointed out; and further, that its function is the same wherever it occurs. It was shown that it is most easily produced in young and growing individuals, and most frequently absent (when absent) in cases where the nature of the disease tended seriously to deteriorate the general health and nutrition of the body. Dr. Godson then read a paper on "Retroversion of the Gravid Uterus."

At the Royal Medical and Chirurgical Society, the now well-worn subject of Myxœdema was again to the fore. Dr. Harley described the disease as a "chronic cold debility," a condition which was subsequent to a form of chronic inflammation long past. It was the result of depressed vitality, and associated with fibroid changes in the lungs. The pleurisy or pneumonia, which always preceded the onset of the disease, invaded the thoracic sympathetic ganglia, and led to secondary changes in them, which changes were the source of the disease.

Dr. Wolfe showed to the Glasgow Medico-Chirurgical Society, on the 4th instant, a case of total blindness from detachment of the retina, in which perfect sight had been restored by an operation performed a fortnight previously. This is the sixth successful case which he has published since he introduced the operation in 1878. Dr. Wolfe thought this case the more remarkable, because after operating on the 14th February, with only a moderate degree of success, he repeated the operation on the 21st, and obtained a completely satisfactory result. The patient could see the time on a watch to a minute, follow with his finger the movements of the small second's-pointer, and see a ring on the finger at a distance of fifteen feet. This is the first time that Dr. Wolfe has ventured to repeat the operation on the same eye. He was encouraged to submit this case to the Society, because he subsequently learned that, previous to his admission to the Ophthalmic Institution, the patient had been treated in another eye infirmary, from which he had a ticket marked "Irido-Choroiditis and Separation of the Retina," so that there could not be any doubt as to the nature of the affection. This corroborative evidence from an independent source, he regarded as necessary in the present condition of the science. For, at the meeting of the French Ophthalmological Society, held on January 24th, 1884, M. de Wecker stated that, after failing in all operative attempts, he had lately been trying revulsive measures by the repeated applications of the cautery (*pointes de feu*) to the surface of the sclerotic, and M. Galezowski recommended that the patient be kept in a horizontal position for many months without a moment's intermission. The President and the other members congratulated Dr. Wolfe upon the success which he had achieved in an affection considered by the highest authorities as incurable. In this congratulation we cordially join. To lay bare the sclerotic, rotate the posterior pole of the eye forwards, and withdraw the dropsical effusions from the retina with precision, just as we tap any other cavity, is certainly not the least of Dr. Wolfe's original contributions to ophthalmology.

A PAPER of great interest was read by Mr. James Thompson, the well-known geologist, on the evening of the 2nd instant, before a meeting of the Glasgow Philosophical Society, on the "Prevalence of Rickets among Children, especially in Glasgow and its neighbourhood." Mr. Thompson stated that a large minority of our rising generation are growing up more or less deformed, partly on account of insufficient nursing while young, and partly, and to a large extent, by reason of the absence of lime in Loch Katrine water, a fact which has already been repeatedly advanced by different medical authorities. He, however, laid greatest stress on the gradual disuse of oatmeal as an article of diet among our working-class population, and the substitution of white bread in its stead, which he characterised as a mass of deception. Another cause for the present state of matters, was the largely increased use of sugar in various forms; the weak legs of the children, he contended, were unable to bear the weight of the sugar-fed bodies. The statistics brought forward by Mr. Thompson, in support of his views were both curious and interesting, and are likely to lead up to some discussion on the subject.

THE members of the Société de Thérapeutique continue to discuss aconitine in its Protean changes. M. Gueneau de Mussy raised two awkward questions at the last meeting, wanting to know what scientific proofs there were for asserting—(1) that crystallised aconitine underwent in time a transformation into another substance with different properties; (2) that crystallised aconitine possessed, according to its mode of preparation, a varying activity. M. Petit attempted to answer these questions by referring to three alkaloids—pseudaconitine, obtained from A. ferox; aconitine, from A. napellus; and japaconitine, from the Japanese aconite. He concluded by saying that the only product to be employed therapeutically with confidence, is crystallised aconitine, prepared from A. napellus by Duquesnel's process. In connection with this question it may interest our readers to reproduce Dr. Stevenson's remarks in the Guy's Hospital Reports. "Dr. Thudichum has shown me a specimen of nitrate of aconitine, made by M. Petit, of Paris, in very white and silky crystals .... which, he informed me, was more potent than Morson's preparation. I regret that an application made by me to M. Petit for a supply, has met with no response; and I regret this the more, as the sole fatal case of poisoning by aconitine, prior to the death of Percy John, was due to the administration of Petit's preparation."

AT a recent meeting of the Académie de Médecine, M. Luys, whose name is well known in England from his able monograph on the brain and its functions, in the International Scientific Series, undertook to show that the cerebral hemispheres were capable of undergoing a limited change of position in accordance with varying attitudes of the body. He maintained that these changes take place in a living organism as well as in a corpse. He considered that these movements might explain a considerable number of morbid cerebral manifestations in the anæmia of convalescence, in seasickness, and in some mental affections. If these experiments are confirmed there seems every probability for believing that the words "activity of the brain," will acquire a new meaning in future generations.

IN a report, read by Prof. Brouardel at the last meeting of the Conseil d'Hygiène et de Salubrité de la Seine, on the desirability of disposing of the remains of bodies after dissection by cremation, he came to the conclusion that public hygiene would have nothing to fear from the incineration of these remains, provided it was done in proper furnaces, so as to prevent the disengagement of all smells; and that such disposal of these remains would entail no ill effects in a medico-legal point of view. The Conseil adopted these conclusions. The sooner the example is followed in thus disposing of the remains from the dissecting rooms, in lieu of the present plan of interment, the better.

SOME months since, M. Quentin, Director of the *Assistance Publique*, issued an offensive circular in which, partly on economical grounds, and partly because in his opinion it was of no use, whether as diet or medicine, he peremptorily ordered the use of beer to be discontinued in the hospitals, and that without consultation with the medical officers as to the effects likely to follow this suspension. This procedure excited much indignation; and profiting by the experience thus gained, the director has recently addressed another circular to all the principal medical officers of hospitals, asking for their co-operation in his attempt at reducing extravagant expenditure. And judging from the figures that the *Union Médicale* (March 13th) publishes, it would seem to be high time that somebody interfered, especially when "no harm will be done to the interests of the patients" thereby. According to these, from 1855 to 1882, the consumption of alcohol increased from 1,256 litres to 77,155; of camphorated brandy from 3,467 to 23,013; of cordial wine from 35 to 3,191; and of natural mineral waters from 1,108 to 18,508. During this interval the number of days of treatment increased from five to seven million—so that while this increase is not extreme, that of the expenses is immoderate. On some points the increase has been legitimate, as in the case of carbolic acid, the consumption of which has risen from zero to more than 5,000 litres; but the increase in the use of pepsin from zero to 43,750 kilogrammes, will naturally excite some surprise. The consumption of sugar has also increased from 102,611 to 201,397, that of the syrup of orange-peel from 205 to 6,942, that of tartaric syrup from 8,925 to 17,055, and that of glycerine from 202 to 10,120, so that it is evident that there must be serious mismanagement somewhere. The gravest abuses have, indeed, been brought to light, from which it is easy to understand "how it is that in 25 years the hospital population have come to drink two million litres of *vin ordinaire* instead of one, and 128,000 litres of *Vin de Banyuls* instead of 17,000, and why the consumption of milk exceeds 2,700,000 litres, at a cost of more than 700,000 francs."

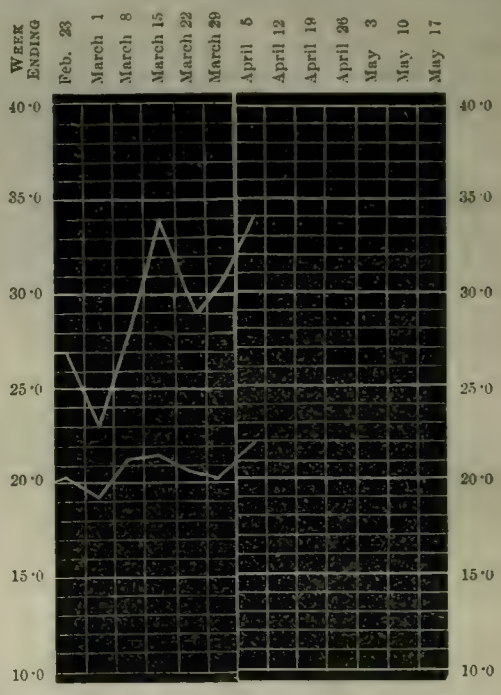
THE seventh award of the Riberi Prize of 20,000 lire (800*l.*) will have as its subject "Embryological

Researches, with especial regard to the Anatomy, Physiology, and Pathology of Man." Printed or manuscript works in the Italian, French, or Latin languages are admissible; and the MSS. will remain the property of the Turin Academy of Medicine. All competing works or essays must be delivered at the Academy before the 31st December, 1886.

Struck by the very large quantity of glucose which the mammary gland secretes at the period of lactation, it occurred to Prof. Paul Bert to investigate the source of this saccharine product. In order to solve the problem, he has been engaged since 1878 in the performance of several experiments, the first results of which he has at length laid before the Academy of Sciences. The experiments consisted in the removal of the mammary glands prior to parturition, or even prior to fecundation, in guinea-pigs, and afterwards in goats. On the 22th of March, a goat having brought forth young under such conditions, it was found that she immediately became the subject of glycosuria, to a great amount, this lasting only for ten days. This fact gives us a right to conclude that the sugar of milk, secreted by the mammary gland during lactation, is furnished by the entire economy and, according to the strongest probability, chiefly by the liver. This last point Prof. Bert proposes to investigate, and communicate the result to the Academy.

An interesting statement was submitted by Dr. Russell, the Health Officer of Glasgow, at the fortnightly meeting of the Town Council, held on the 7th instant, in regard to the recent outbreak of small-pox in that city. Of the twenty-four cases of this disease recorded for the fortnight ending March 28th, Dr. Russell reports that eleven were associated in two groups, of which the first comprised six cases, all confined to a carter and his family, residing in the northern district; while the second included five compositors, all employed in one office, but living in different parts of the city. An important conclusion is arrived at from this investigation by the health officer to the effect that any cutaneous eruption should be regarded with suspicion, not alone by parties who may be attacked, but also by their employers and foremen, as within a short period a lamplighter on his beat, a carter at his horse's head, and an apprentice in a printing office were found with the eruption on them. We would qualify the health officer's conclusion by suggesting that *medical practitioners* should also be suspicious of cases of pustular eruptions on the face and other parts of the body, and if doubtful in their minds of the nature of the case, should call in the health officer, or some other capable medical man, and not allow cases of small-pox to go about under the belief that they are cases of chicken-pox.

Last week's health return for London is the most unfavourable one that has been published this year, the general death-rate being 21·9 per 1,000. The total number of deaths was still, however, 174 below the ten years' average, though the number of zymotic deaths exceeded the average by 16. The fatal cases of small-pox numbered 13, less than might have been expected from the increase in the number of cases recorded last week. There were 293 small-pox patients in the hospitals at the end of last week, compared with 284 on the previous Saturday, but only 39 new cases were admitted in the week. The mortality from measles again increased, but not materially. The fatal cases of whooping-cough rose to 125, and accounted for nearly half the total number of zymotic deaths. It will be seen in the chart that the



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the last six weeks of the last quarter, and the first week of the present quarter.

zymotic death-rate has again reached the point at which it was three weeks ago. In both cases, the rise was due to increase in the deaths from whooping-cough, due to a few cold nights, and not to any real spread of epidemic disease.

A fire of rather an alarming nature occurred at the Glasgow Royal Infirmary early on the morning of the 3rd instant. Immediately behind the medical wards of the infirmary, which form the southern portion of the establishment, there is a one-storey building which is used as a store, and it was in this building that the fire broke out about 4 p.m. At the time the alarm was given there were a large number of patients in the medical wards, and the utmost alarm was felt by the officials that the fire might spread into those portions and endanger the lives of the inmates. The superintendent, Dr. Thomas, in conjunction with the resident medical assistants, nurses, and other officials, exerted themselves to their utmost, and succeeded in removing the patients from their perilous position into one of safety in other wards which were at a distance from the locality of the fire. In the meantime a number of fire engines arrived and succeeded in confining the fire to the store-room in which it had originated, the contents

of which, as also the roof and many windows in the wards and staircases, were destroyed. The amount of the damage done is estimated at about 400*l.*, which is said to be covered by insurance. The origin of the fire is unknown.

We have to note the death, at a ripe old age, of a man who had won the sympathy and respect of a large number of the profession, Mr. Peter Squire, the *doyen* of pharmaceutical chemists, if not the founder of pharmaceutical chemistry. Born in Bedfordshire near upon eighty-six years ago, he was brought up in the country, and to this he was indebted for his keen observation and love of rural objects, for his early interest in botany, and his leaning to the cultivation of natural science. On coming to London, he applied his chemical knowledge so successfully to the improved preparation of drugs, that the colour and odour of each plant became recognisable in their extracts and preserved juices. At the same time he was actively engaged in the endeavour to arrive at ready means for obtaining instantaneous light, that might supersede the flint, steel, tinder-box, and sulphur matches then in use. A jet of hydrogen thrown on to spongy platinum, and little bottles of phosphorus and chlorate of potash preceded the common lucifer match, and many of his experiments aided this result. It was, however, in the pharmaceutical laboratory that his closest and most exact work was done. The energy and vivacity of his nature was applied to this, as to all his undertakings, with unwearied industry. He well earned the appointment of Chemist to the Princess Victoria, and that of Chemist in Ordinary to Her Majesty on her accession to the throne. He was one of the earliest promoters of the Pharmaceutical Society and its journal, and the author of a paper on "Preserved Juices," which appeared in the first volume of that journal, for 1841. In 1851, he published the three Pharmacopœias of London, Edinburgh and Dublin, in such a form as to show their discrepancies side by side—differences which he thus helped more than any other one man to remove, and to lay a basis for a National Pharmacopœia. The "British Pharmacopœia" at length was completed in 1864. The Companion to it, in twelve consecutive editions, showed how thoroughly in every detail can be seen the hand of a master. Till early in the present year, no lack of energy, or any diminution of memory, or of faculties remarkable for strength and precision, was observable; then, signs of approaching failure of bodily strength gradually appeared, and he passes away in the fulness of time, honoured and beloved.

The recent fire at Messrs. Pardon's, in Paternoster Row, which, had it happened a few months ago, would have been seriously felt by this journal, will, we regret to hear, delay the publication of the second and concluding volume of Dr. Morell Mackenzie's work on "Diseases of the Throat and Nose." Had not one copy fortunately been in the possession of the author, four years of unremitting labour would have been entirely lost; but the reprint will be carried out by Messrs. Pardon as rapidly as possible, and the volume, which was on the eve of publication, will, it is hoped, be brought out in three or four months.

Mr. Bright has been ill, and is recovering under the innocent ministrations of a homœopath. A few months ago Sir William Siemens was attended in his last moments by a homœopath. A few years ago the unhappy circumstances attending the death of Lord Beaconsfield called general attention to the fact that for years the brilliant statesman had reposed his confidence in a homœopath. His able lieutenant, too, Earl Cairns, the papers tell us, is attended in his illnesses by a member of the same fraternity. Here we have four of the ablest men that this century has produced all giving in their adhesion to homœopathy—four men, too, of such diverse character that it is difficult to find in them a single point of resemblance except this, that they solemnly expressed their belief by most tangible tokens in one of the most baseless superstitions that has ever found a following. It is futile for the regular practitioner to console himself with a sneer, and explain the apparent infatuation of these celebrities on the principle, *Similes similibus curantur*. Homœopathy is a superstition, and its followers are happy in holding tenets without a rag of evidence to support them But it would be absurd to credit men like the late Lord Beaconsfield and Sir W. Siemens with a similar kink in their brains.

In the old days it was the habit of orthodox believers to account for schism by assuming innate wickedness in the schismatics, or else to attribute it to the machinations of the Evil One. Modern enquirers, with more reasonableness, prefer to explain it as the result of some imperfection in the orthodox creed or its ministers. So in this matter of homœopathy, is it not quite as reasonable to suppose, that the defection of these four celebrities from medical orthodoxy is due to faults on the part of the orthodox, as that it is to a result of the overwhelming attractions of the homœopathic belief, or of the imbecility of the schismatics? At any rate, we ought not to rest until we have assured ourselves that there is no fault in us. Can we assure ourselves that the trades-unionism, which is too manifest in our ranks, that the sacrifice of patients' interests to an effete etiquette, that disloyalty to our consciences, and lapses into quackery have had nothing to do with that disgust with the orthodox profession which is seen in the rebellion of such minds as those of Lord Beaconsfield, Sir W. Siemens, and John Bright? If we can, well and good; if not, then it is high time that we mended our ways. Let us mend them!

The exact *rationale* of nerve-stretching, and how it is that harm does not frequently result from the tearing away of some of the nerve fibres from their attachment to the spinal cord, must have exercised the minds of many people during the last few years, since nerve-stretching has been tried for every imaginable form of nerve disorder. A good explanation of the impunity with which this little operation is daily performed is given by Mr. Cantlie in a paper read before the Medical Society of Charing Cross Hospital, and published in the last number of the *Bristol Medico-Chirurgical Journal*. He there says that some years ago, when dissecting the sciatic nerve of a frog, he noticed a peculiar but very decided spiral or coiled

appearance of the components of the nerve trunk. On stretching the nerve the coiling disappeared, but on relaxation it appeared again. He had surmised at the time that it had to do with permitting the nerve to accommodate itself to the movements of the hip-joint. He has since examined most of the nerves in the human body from this point of view, and found the same spiral or coiled appearance in all the nerves which are in a position to be stretched. It was especially well marked in the nerves of the tongue and the penis. Nerves running through long canals did not show it. The nerves of the hand and foot lose the condition when near their extremities; thus the median and ulnar cease to show it about half way down the fore-arm, and the nerves of the leg, markedly the anterior tibial, have no trace of it. The nerves about the knee and elbow joints, where there is plenty of movement, show it well.

We have received the following from a correspondent:—It will possibly interest the readers of the *Medical Times* to hear that a very admirable portrait of the President of the College of Surgeons has been painted by Miss E. M. Merrick, which, if the verdict of his friends be accepted, should gain a distinctive position amongst the works of the rising artists of the year at the forthcoming Academy Exhibition. The artist, who has already achieved considerable distinction, both at last year's exhibition, and at the exhibitions of the Society of Lady Artists, gained last year the first prize at the Royal Academy School for a study from the life, and was for this reason selected by Professor Marshall to paint his portrait from among the students, to whom he is the popular lecturer on anatomy.

J. writes to us as follows: — In noticing the *Memorials* of Mr. South (April 5th, p. 461), your reviewer says, "There are next to no blunders." There is one, quite excusable, which would be detected by none but old St. Thomas's men. Mr. South mentions his being fetched to the hospital "by guard," and the editor explains in a note that Mr. South was surgeon to a railway company. I believe this is a mistake, however; the word "guard" should be "Gard." This was the name of the surgery-man, whose duty it was to summon the surgeon or assistant-surgeon to accidents.

A great injustice is done to many nervous sufferers because their medical advisers *lack imagination*. They would do anything to help a patient in a fever or in a pneumonia, but if he suffer from symptoms wholly "subjective," or which cannot be put into very definite language, the doctor is tempted to say it is all nonsense, or that he cannot understand his complaints. He tells his patient to "throw it off," or to "make an effort to feel like other people." The remarkable symptoms described by Mr. South, which were quoted in this journal last week, in view of the great interest recently aroused in this subject by Dr. Clifford Allbutt's lectures, have led us to some such reflections as these. We would suggest to our readers that some kinds of ailments would be better treated by them, because better realised, if they would store up in their memories the experience of those moments which have intruded, occasionally at least, into the lives of most men, namely, those moments of irritation, fretfulness, and "nervousness," which have followed overwork, anxiety, or fatigue. Strong persons pass rapidly through these phases, but how pitiful must be the state of those who are "chronically" in such a state! Persons, whose nerves are always "highly strung," who only keep steady and tolerant by incessant watchfulness and hard effort, are indeed sufferers, although they have no "physical signs." How far such persons can slowly modify their physical habits, so as to alter their physical states, is too abstruse a question for us at present, but that such states are real enough and distressing enough must, we repeat, have been revealed at times, if but by glimpses, to every man and woman. To remember our individual experience of these times of fidgets and "hyperæsthesia," would humanise the practice of all of us.

Those who are interested in the College of Surgeons will be pleased to learn that the Council have awarded a sum of 500*l.* to Mr. Trimmer, in recognition of the zealous activity he has displayed during the twenty-five years that he has been in their service.

In the *Alienist* and *Neurologist* for January is an excellent article by the editor, Dr. Hughes, upon the opium habit—the opium psycho-neurosis he calls it—which seems to be of very much more frequent occurrence in America than it is here. The treatment is fully described, and the author gives the assurance that "it is surprising with what little real suffering a patient, who has tried so often in vain to relieve himself, can be conducted through the successive steps leading to the abandonment of this powerful drug, if it be not too precipitatively done." The same number of this quarterly is enriched by a translation of Professor Tamburini's important paper on "Doubting Insanity," and by an article of the late Dr. Ray, on "Testamentary Capacity."

The *Journal of Mental Science* for this quarter is a good representative number, the original articles representing all phases of work in the specialty, from the most minutely and severely practical to the highest and driest of speculative writing. To the former class belong Dr. Savage's paper on the "Constant Watching of Suicidal Cases," and Dr. Mickle's article on "Rectal Feeding and Medication"; while the latter is represented by Professor Herzen's essay on the "Physical Conditions of Consciousness," and a fourth instalment of Dr. Mercier's series of papers on the "Data of Alienism." Dr. Major and Dr. Warner contribute articles which occupy a middle place, and have titles too long to be quoted. The lithographs of brains, by which some of the clinical cases are illustrated, deserve special commendation for their artistic merit.

Occasionally some details of more than passing interest are to be gathered from the annual reports of Medical Officers of Health. Dr. John Shea, in commenting upon the sanitary history of the borough

of Reading, for the past year, in connection with increase of population, states that at the beginning of the sixteenth century the population of the town of Reading numbered 4,700, and that it took 200 years for that population to double itself, since, in 1801, the inhabitants of the town were returned as 9,742. In more recent times, however, about thirty years has been sufficient to double the number of its inhabitants; thus, in 1850, Reading contained 22,716 people, while at the present time the population is calculated at 45,000. In the year 1831, the death-rate of Reading was twenty per 1000; in 1841 it was 24·5; and in 1849 it rose to thirty. The average of the last five years, however, gives a rate of 17·32 per 1,000, and that for the year 1883, just completed, is still lower, viz., 15·90 per 1,000.

THE LUMLEIAN LECTURES.

The desire for finality in science and philosophy, which is, perhaps, a pardonable human weakness, is evinced in a marked degree by the medical mind. We readily and perforce recognise the *vita brevis*, but in our eagerness to settle important questions, the no less inevitable *ars longa* is apt to fade from our mental vision. Considering the main reason of our existence as would-be healers of men, and the important dependence of our practice on the notions we entertain as to the causes of disease, this tendency to rush at conclusions may be largely excused on the one hand, while it is equally to be deplored on the other. The long-vexed question of the causation of consumption affords a salient example of this tendency to draw great conclusions from inadequate premises, and most especially so in its latest phase in the present day, when the specific character of the disease bids fair to be established by science, and the over-practical physician rushes at once to the conclusion that its contagiousness must be taught as a matter of course. Dr. Andrew, in his clear and thoughtful lectures, which appear in abstract in our present issue, has shown in a most masterly manner how such a complicated question as this should be discussed in the dry light of intellect; for, search through his arguments as we will, we can find no trace of a tendency to suppression of fact, or any taint of party strife. He has not attempted to settle, once for all, the question of the ætiology of phthisis; nor, indeed, has he advanced any novel suggestion: but he has done far better, in marshalling before us in a complete form the best accredited facts relating to the occurrence and the history of this disease; and taking both the oldest and the newest knowledge into fair consideration, has endeavoured, with considerable success, to demonstrate their rational connection.

Dr. Andrew's position, with regard to the proved relation between tubercle and the bacillus of Koch, will scarcely now be questioned by any, and though it may be said that more inoculation experiments are still to be desired, it may be admitted with him that the entry of the bacillus from without into the organism is a necessary factor in the production of tuberculosis. "No tubercle without bacillus" may already, indeed, without much fear of contradiction, be assumed as a pathological axiom. But doubtless since this discovery has been made, and the observations repeated by many ardent stainers of microscopical specimens, there has been a great tendency to teach that an ever-virulent germ is the only cause of phthisis, and to ignore, at least by implication, the probably no less important factor of the soil which may be necessary for its life and action. Germs of disease are too readily looked upon as all alike, and even the newest of them are placed in the same category with those whose effects, at least, have been long familiar to us. But Dr. Andrew emphasises very strongly his belief in the existence of the well-known influences of dampness of soil, imperfect ventilation, heredity, exposure to vicissitudes of climate, various occupations, and other factors as, one or more of them, contributing, for the most part necessarily, to the production of phthisical disease. Regarding these as predisposing causes to the affection, on an overwhelming amount of evidence, he freely admits that one and all are inadequate to account completely for its distribution or its anatomical and clinical characters, and welcomes the discovery of the bacillus as supplying a link which may perfect the ætiological chain. This theory seems especially valuable as throwing light on the undoubtedly close clinical relationship that exists, as the lecturer insisted, between scrofulous disease, phthisis, and acute tuberculosis—a relationship which being difficult to explain on the recently fashionable "inflammation" theory of caseous phthisis, was often in consequence denied. We seem, indeed, to have ground for hoping now, that as soon as this bacillus can be said to have fairly won its position, the fight between the "grey" and the "yellow" will no longer rage in tubercular pathology.

Dr. Andrew's teaching that the bacillus of tubercle can probably thrive in certain conditions only, is supported by clinical facts, and is also quite in accord with scientific knowledge of bacteriology. As was pointed out last year in a leading article in this journal, entitled "Bacteria and Disease," there is great reason to believe in a varying degree of specificity in many of these organisms, as illustrated by different forms of the yeast-fungus, and the probable identity, as shown by Buchner, of the so-called Bacillus Anthracis with a harmless form occurring in putrefying vegetation. This would serve to explain the wide-spread immunity from phthisis enjoyed by many who must be frequently inhaling the free organism.

Following on these considerations, Dr. Andrew proceeds to argue, in support of his main thesis, that phthisis is not, properly speaking, contagious. Comparing the disease in many points of importance with ague, he says that specificity does not, by any means, imply contagion; and professing most clearly his belief that phthisis is a specific febrile disease, and is indeed entitled to rank as such apart from the discovery of the bacillus, he goes as far as to say that the facts on which the specific theory is based are opposed to the notion of the contagious character of the affection. He certainly succeeded in showing that, while it is allowed that some specific febrile diseases are directly communicable from the sick to the healthy, some indirectly, and others not at all except by artificial means, there is no reason why phthisis should be placed in the

first of these categories. The lecturer's comments on the reported cases of contagion seem to us especially pertinent, and, with his evidence of the greater probability of local infection in apparent cases of this kind, are worthy of the most careful study.

There is no evidence of any *arrière pensée* or prejudice in these lectures, though Dr. Andrew himself pleads guilty to the possibility of bias from the aggressive position he has chosen with respect to the notion of contagion. On the contrary, the careful statement and arrangement of his facts bear witness to a strictly scientific tone of mind, not yet too common in the medical profession, while his logic, unmixed with controversial sophistry, would do credit to any professor in the University of Oxford, of which Dr. Andrew is so distinguished a graduate.

THE PHARMACOPŒIA AND NEW REMEDIES.

From the recent Report of the Pharmacopœia Committee of the General Medical Council, we gather that no further suggestions are invited towards the completion of the new Pharmacopœia. "All the documents and reports have been placed in the hands of the editors." The Committee feel satisfied that the information, now in their hands, will be sufficient to render the next edition of the *British Pharmacopœia* worthy of the approval of the Council, and of the profession." So ends the report received and printed in the minutes of the meeting of the General Council, on March 27th. The communications from the different medical and pharmaceutical authorities consulted seem to be numerous enough, and even after the "most attentive consideration" given to them in the three or four meetings of the Committee held since May, 1882, must form an embarrassing amount of material to be thrown upon the hands of the editors. But, surely, this function of the Medical Council and of this Special Committee is not performed by merely sending round an appeal, and stopping it when the mass of matter accumulated is likely to become unmanageable? Are the editors to receive no directions as to what shall be put in, and what shall be left out of the Pharmacopœia? The list may well be closed against new claimants for admission to it; the information, gathered from so many quarters, is doubtless ample, and no new suggestions are needed; but, to make the new edition worthy of general acceptance, the Council must decide upon what shall be adopted and what rejected, and the Committee must exercise a continuous vigilance so as to give definite instructions as to what is advisable on fixed and clear principles.

Conspicuous among these should be a firm opposition to any large increase in the number of officinal preparations. The Pharmacopœia of 1867 included one hundred and fifteen articles not contained in that of 1864. Ten of these, too hastily rejected from the former edition, were simply reinstated; these are the acetum and oxymel of squills, sulphate of atropia, the compound infusion of gentian and of orange, the solutions of the acetate and citrate of ammonia, the brandy and egg mixture, and the *spiritus ammoniæ fœtidus*. Ten useful additions were gained in carbolic acid, bromide of ammonium, carbonate and ammonio-citrate of bismuth, oxalate of cerium, the liniment of iodide of potassium with soap, an acid solution of arsenic, calabar bean, cacao butter, and a syrup of rhubarb. Among the useless additions may be mentioned canella, buckthorn, lettuce, pyrethrum, and sumbul; an iron mixture, five extracts, three or four pills, six tinctures, and all the four preparations of orange wine. The Medical Council is authorised by Act of Parliament to publish a book "containing a list of medicines and compounds, and the manner of preparing them;" without some care against the multiplication of new forms this book will be so encumbered that one or several smaller publications will again become necessary for the guidance of the medical practitioner in prescribing, and for the use of the student in acquiring a knowledge of the remedial agents in use. The preparation of orange wine may again be left to our grandmothers' *recipes*, and by the end of the century we may be much as at its commencement perhaps, with some safe and many very unsafe acquirements. The traditionary hold of harmless things is of slow growth and slow decay, and we may be content that it is so. Of more active novelties the danger is sooner over; but as one disappears others push forward and raise commotion enough to attract attention. This is specially true of new medicines. If we have passed by digitalin we have to meet nitro-glycerine, hyoscyamin, gelseminum, apomorphia, and perhaps monobromide of camphor. On looking to what has recently been said of these things, we are not surprised to see epilepsy appealed to, as it has been time out of mind in support of most doubtful remedies; but in these days of a more exact pathology to find paralysis agitans curable by any of them is amazing. Yet this has been claimed for hyoscyamin. Again, an atom of bromine replaces one of hydrogen in camphor, the compound is said to depress the circulation, respiration, and temperature, "large doses cause clonic convulsions and muscular trembling," and then it is recommended in five grain doses in whooping-cough of children, for teething and hysterical wakefulness. The nausea and prostration, resulting from small doses of apomorphia, we regret to see put in action against hysterical disturbance; and, after great advance for many years in the care of the insane, we have come now to hear of "chemical restraints" in drugs, and an extended place asked for them in the Pharmacopœia. We conclude for the present with one word as to doses. Under this head the quantities stated in the preface are to represent average doses, in ordinary cases, for adults; this is to be considered in any proposed lowering of the dose. But if we are to order one grain of the hypophosphites, then only a mere fraction of a grain would be given to children, from which we should obtain but slight results in the cases where they otherwise would be most useful. On the other hand, too large a dose of the extracts of aloes is given in the present Pharmocopœia. In the nine formulæ for pills containing aloes, from one to two grains only of aloes is contained in each pill; now the dose of the extract is given as from two to six grains, yet the extract is nearly, and that of Socotrine aloes quite, twice the strength of the aloes used in the pills.

HOSPITAL OUT-PATIENT REFORM.

II.—From a Professional Point of View.

On a former occasion we discussed the question of Hospital Out-patient Reform from a public point of view, denouncing as a principle the wholesale distribution of gratuitous medical charity, suggesting the propriety of encouraging all classes of the community to contribute, in proportion to their means, towards the hygienic as well as to the other necessities of life, and maintaining that this could be successfully carried out in practice to the advantage and profit of all concerned. There is another aspect of the subject which, from the professional man, merits attention, namely, the present state of hospital management from the physician's point of view. We shall not attempt to enter into all the topics which might be discussed under this heading, and among others, the general principle, that it is an injustice to require the members of any vocation to perform arduous and responsible labour without remuneration, and thereby inflict an injury, not only on themselves but upon their brethren, who have to live by the exercise of their calling. We shall confine our observations to the business relations which exist between the medical staff of a hospital, and the out-door department to which it is attached.

The duties of medical officers to our public institutions are performed gratuitously, and without question of direct pecuniary return. On the impulse of pure philanthropy, which prompts this action, it is not proposed to dilate, further than to remark that if the members of the medical profession, as men, cannot claim more than their share of instinctive benevolence, when circumstances have required it, they have not been found behind-hand in disinterested services to their fellow-creatures. It must, however, be granted that the eager desire to obtain hospital appointments, displayed by youthful aspirants to distinction, cannot be attributed entirely to this motive. The class of men who seek such posts are, as a rule, those actuated by ambitious aims in life, who desire to raise themselves to the higher grades of their calling, and who, by a more elaborate education and extended experience, hope to fit themselves to occupy that position unattainable by the ordinary ranks of their profession. This, they believe, will be mainly realised by their association with a public institution to which, for the material advantages they expect to receive, they are willing, in return, to give their gratuitous professional services. At the present time a good hospital appointment is sought for by the young physician or surgeon for the following reasons:—First, It is supposed that the prestige of belonging to the staff of such an institution, and the association with distinguished colleagues is in itself an advantage, that it stamps a man as following an honourable path in his profession, and is, therefore, likely to make him favourably known to his fellow-workers and the public. Secondly, It probably connects him with a medical school, and thereby gives him the opportunity of becoming a teacher, and thus distinguishing himself amongst the younger members of his calling. Thirdly, it provides him with clinical material, through which he can not only perfect himself in the art of his profession, but by the accumulation of experience and observation thus obtained, can further the science of medicine for his own as well as for the general interest.

We have, however, seriously to consider whether, under existing circumstances, this bargain between the medical officer and the public institution is impartially carried out on both sides. In the case of the full physician it may be said that, on the whole, he has no serious ground of complaint. He possesses a distinguishing title, his position is independent, and his duties much as he chooses to make them; the material at his disposal supplies all his requirements, and is practically under his own control and management. In return for these advantages he willingly gives his professional services to the inmates of his wards. The position of the so-called assistant physician is, however, very different, and urgently necessitates reform. Every year, owing to a variety of circumstances, his office becomes more laborious and irksome, and as the demands on his time and attention increase, the corresponding advantages he is supposed to receive in return, diminish. The very title he holds, and which he may retain till advanced in years, is a misnomer, as he assists no one, and his duties are as responsible as those of his nominal seniors. In modern times, such are the number of smaller hospitals which have sprung up in all directions, that the merit of being a hospital physician has become greatly diluted, and almost any one can now obtain an appointment of some kind which, with the public, will equally entitle him to this distinction. The prestige, therefore, of such a position is materially impaired; association with even the most prominent hospitals, brings little direct benefit to their junior staffs, and association with the smaller ones, none at all. Such consideration would be of less moment if the most important object at which the young physician aims was fulfilled, namely, the opportunity for obtaining clinical material for teaching and scientific observation. The present state of management in out-door departments is totally subversive of any such anticipations. At most of the London hospitals, the doors are thrown open to the public without limit or selection of any kind, and, as a consequence, multitudes of persons present themselves for treatment, to all of whom the assistant staff is expected to direct attention. The total absence of any form of restriction encourages flocks of patients, especially women and children, suffering from the most trivial or imaginary complaints, to crowd the waiting rooms, which thus become the lounging places for all the idle gossips of the neighbourhood who are gratuitously entertained at the public expense, and enabled to foster and satisfy their ignorant cravings for "doctor's stuff." Not to speak of the unnecessary physical and mental labour thus entailed upon the doctor, is it not perfectly monstrous, that the physician, a man theoretically of superior attainments and experience, should have to expend his time and energies in wading through this mass of undigested and useless material? He thereby performs the very lowest class of general practitioner's work, and only differs from him in the fact that he is not paid for his services. As the report of 1870 on

Hospital Reform, already referred to, justly remarks, "An inordinate number of trivial cases wastes the time of the consultant, wearies the attention of the student, and fosters a habit of hasty diagnosis and careless observation, which tend to erroneous and ineffective treatment." This herding of people, clamouring for attention, further prevents the physician from giving to those seriously ill that care and thought which their cases merit, it is totally inimical to clinical instruction, and absolutely subversive of all scientific observation. "In fact, out-patient work, as generally conducted, neither conduces to the sound advancement of professional knowledge, nor to the advantage either of the student or the public."

The moral of these general reflections is, that while the assistant physicians at our hospitals fully carry out their side of the bargain, by the expenditure of their time, labour, and skill, in behalf of the sick poor, they are not rewarded by an equivalent return for their services. Not only do they receive no pay or any direct material advantage, but even the *quid pro quo* for which they may legitimately look in the shape of clinical material, with opportunities of utilising it, is in great part denied them.

The reformation of this unfortunate situation is one of considerable difficulty and delicacy, as when attempts are made in that direction by medical men, they are confronted with the retort that their motives are those of personal interest, and that if they are not satisfied, they can resign the position they hold. The adoption of this procedure would in no way remedy existing evils as if the posts were vacant one day, they would doubtless be refilled the next. The public, under these circumstances, will never entertain the idea of remunerating hospital staffs, or of mitigating their labours, so long as the appointments they offer are so eagerly longed for, and so readily accepted on the present terms. Any hopes of amelioration in the future must, therefore, mainly depend upon the action of the profession itself and were sufficient firmness and unanimity brought to bear on the question, success would inevitably follow. Without, however, anticipating unnecessary difficulties, we trust that the time soon will come when, by the united efforts of lay and medical men, the present position of out-door patient relief will be placed on a better footing, so that it may work to the satisfaction of all concerned. Whether this is to be effected by an extension of the provident system, by the institution of small payments, or by other means, remains yet to be practically demonstrated.

CLINICAL PAPERS.

IX.—Bone-setting.

The bone-setter is still able to ply his trade successfully! This, we think, no one who has any surgical experience can deny. It behoves us then to see in what measure we fail to meet the requirements of our patients. For failure there must be, if good is done that we have been unable to effect, and common justice demands that we should acknowledge such to be the case. We pride ourselves on the fact, patent to our anatomical knowledge, that the bone-setter's diagnosis is hopelessly wrong. And spending our wrath on this proof of his absolute ignorance of the structure of the particular joint in question, we forget to enquire wherein he has succeeded in securing the patient's approval. That the joint could not have been dislocated we are absolutely sure, and an examination subsequent to the supposed reduction only confirms our original opinion. The same fracture or other injury exists, just as we left it. We confidently reiterate to our inward satisfaction, "No, it is as I stated to you at first, a fracture into the elbow-joint." The natural answer which we might expect, did we not feel injured at the trick which it is hopeless for us to attempt to explain, meets us at once—"Well, I don't know whether it was '*out*' or not, but one thing I am sure of, and that is, that I could not get my hand to my mouth before, and now I can." Making every allowance for that large contingent of the public that prefer to place themselves in the hands of an irregular practitioner — a term which appears now to be the euphonious title of a quack—there still remain a goodly number who follow the orthodox treatment to the end, and yet derive considerable benefit from the treatment subsequently employed by the bone-setter.

Then, again, there are those intermediate cases in which, not satisfied with the progress they have made, patients run off to the bone-setter before their treatment is finished, and there undergo the very movements which were about to be employed by their regular doctor. Such cases are the most trying of all to the painstaking surgeon. For a new version (particularly an unauthorised one) of the nature of the injury he has received is always pleasing to a mind that knows nothing of the possibilities; and the absolute and sudden change which would have followed in the ordinary course of treatment under the regular practitioner, if he had waited a little longer, appears miraculous in the hands of this new prophet, and confirms at once the wavering mind, which before was only half convinced of the truth of the new diagnosis. To the patient it matters little what was the exact condition of affairs. "Before I was lame, now I can walk." Therefore the man who made him walk must be right. Let us then consider the nature of these cases. They may, we think, be roughly divided into two large classes. Firstly, those that are at once and completely cured of their disability, and require only free use of the limb to get back all its functions. The simplest illustration of such a case is where, after dislocation of the shoulder and its reduction, the arm has been kept too long at rest, and adhesions have formed between the folds of the synovial membrane. If seen sufficiently early, one vigorous and forcible movement of the arm is sufficient to cure the patient, provided he will consent to exercise it regularly himself after this has been done. The same occurs after fracture of a long bone. The neighbouring joints may become stiff, and require these violent movements to set them free. Secondly, there are the more difficult and interesting cases where joints are more or less hopelessly fixed. And here it is where the good bone-setter shows so much *savoir faire*. He differs at once from the diagnosis of the original practitioner, and if he thinks a favourable result likely to follow from rough manipulation, he then and there

gives a sudden and violent movement from which all subsequent improvement is supposed to take its origin. He states that he has reduced a dislocation, and he is believed, because so much improvement follows the manipulation. We may safely state that if everything had been done which surgical art can contrive for the benefit of the patient, such reduction as he calls it could not have taken place. The fact being that if the patient obtains an atom more movement after his visit to the bone-setter he naturally, in his ignorance, believes what he is told—that reduction of an unrecognised dislocation has been accomplished. There is no doubt at all that many of these cases fall into the hands of the irregular practitioner through the apathy of the ordinary medical attendant. The latter has done a great deal for his patient, has guided him through a troublesome period of illness, after accident, to convalescence, and thinks naturally that the man ought to be thankful he is not worse. The amount of discomfort which the patient suffers he treats lightly, for to him it appears insignificant in comparison to his previous condition. If the practitioner would only follow his case up to the very last, and persevere by passive movement, friction, shampooing, &c., we should hear less of these marvellous cures. The bone-setter has merely done what the medical attendant ought to have recognised was necessary or advisable. He has liberated the joints, stiff from their long confinement in splints, by free passive movement. Or he has given an anæsthetic, and forcibly moved a seriously damaged joint—one in which it was rightly thought advisable at the time of the accident to procure anchylosis on account of the severity of the inflammation. But there are many cases in which the inflammation having subsided, a little movement may be re-established. Now, how does the bone-setter recognise the condition in which he may safely apply his method of treatment. Of course, he occasionally makes mistakes, and employs passive movement, when continued rest ought to be enjoined, and in this he more frequently errs than his more scientific brethren. But, speaking generally, he judges rightly that, if the joint is cold to the touch and the skin in a peculiar waxy inactive condition, the forcible movement may be with safety employed.

There are other cases in which great benefit is undoubtedly obtained by free and forcible movement. Take, for instance, an old and chronic case of sciatica, which has of late years been treated by nerve stretching. The explanation of the improvement that follows this treatment lies in the freedom given to the nerve trunk in its bed by the forcible stretching. The inflammatory infiltration in the sheath of the sciatic nerve has led to an unnatural rigidity, causing constant pain and annoyance to the sufferer, and this the operation overcomes. By forcibly flexing the thigh on the abdomen, the same stretching may be accomplished, as in the operation, particularly if an anæsthetic be given. Such a simple expedient ought not to be left to be used by the unqualified ranks of our profession. Instances without number could be given, did space and time permit, in which inflammation, long since subsided, had left its mark in the form of impaired movement in a joint which has not itself been involved. Not one disease, but many, may bring this sequel in their train. And yet how frequently such cases, which can be so easily cured of their disability, fall to the lot of the bone-setter—a man who simply, be the complaint what it may, puts every joint of the limb through all its varied movements. If there be the slightest imperfection in one direction he overcomes it by a wrench, and the complaint, odd though it may seem, frequently ceases.

The object, then, which we should have in view, is to more carefully guard our patients to the end. We are certainly less likely to do the injury which occasionally falls to the lot of those who visit the irregular practitioner; and if we systematically look for those slight impairments in function, and work away at passive movement, with and without an anæsthetic, we shall be less liable to be met with the humiliating reply, when our patient has "sought further advice," "Well I could not do this before." K.

HEITZMANN'S HISTOLOGY.[1]

[First Article.]

In his preface, the author says:—"In presenting this book, the result of ten years' intense labour, to the public, I am aware that not all the facts and conclusions here laid down will meet the immediate approval of professional microscopists." Dr. Heitzmann has for many years, in scattered communications, been an opponent of the cellular pathology, which Prof. Virchow inaugurated. His writings are well known on the Continent, and though, perhaps, less familiar here, some of his many histological observations find mention in English books. The work of anyone who earnestly devotes ten years to laborious research is certainly worthy of most attentive consideration, and we cordially welcome the present volume as the clear statement of the views of one who is entitled to respect, even though we may not be inclined to accept all his conclusions. Dr. Heitzmann has established a School of Histology in New York, to which he has attracted a large number of pupils; the individual researches of many of these are embodied in the present work, and some of them are of extreme interest.

The first chapter contains a description of histological methods, but with the second chapter Dr. Heitzmann plunges at once into his subject. This chapter is entitled "General Properties of Living Matter," and was first published in 1877. In it the author defines the smallest molecules of living matter—"plastitudes," each composed of at least five atoms, C.H.O.N.S., endowed with a peculiar motion "of relatively short duration" or "life," a change of which motion is disease; a cessation, death. The properties of living matter are motion and reproduction. This motion is not that of which heat, light, and electricity are examples, but a certain kind of motion dependent on the irritability and contractility of living matter enabling it to work "at least to a certain limited degree, against the law of gravity." "It is controlled by complicated laws which we term the 'will' and the 'spontaneity' of living matter." Motion is either "amœboid," changes of shape, or "locomotion," changes of place, both peculiar

[1] "Microscopical Morphology of the Animal Body in Health and Disease." By C. Heitzmann, M.D. Trubner and Co.

to the structure of living matter. Living matter exclusively possesses the power of "growth" and "generation." This latter is either by "division," "gemmation," or "endogenous formation." The offspring resembles the parent, because "the germ of every living individual contains plastitudes of all its ancestors; so that these are bodily regenerated in their offspring, simply because bodily particles are preserved directly from generation to generation." This is the theory originated by Elsberg, which the author prefers to Hering's assumption of "unconscious memory," and Häckel's "perigenesis," or Darwin's assumption of the accumulation of sexual granules formed of granules of the parent. According to the author it is the only one which explains how ancestral peculiarities reappear in the second or third generation. A brief *resumé* of the cell theory from the time of Dujardin in 1835, up to 1872, when Max Schultze's definition of a cell as a lump of structureless protoplasm was accepted, concludes this chapter.

The third chapter discusses "The Arrangement of Living Matter in Protoplasm," and has previously appeared in German in 1873. In it the author demonstrates the reticular nature of protoplasm; the nucleus, nucleolus, granules and connecting reticulum, being the living contractile matter, suspended in a non-living, non-contractile fluid. An investing membrane does not exist; vacuoles are accumulations of fluid surrounded by a wall. The nucleus moves passively. These views have been accepted unreservedly by histologists. Two original papers close this chapter. One on "The Structure of the Blood Corpuscles of the Oyster," by H. M. Harlbutt, and the other on "The Structure and Growth of some Forms of Mildew," by Wm. Hassloch; both confirming the views of Heitzmann on the fibrillar structure of protoplasm.

The next chapter, which deals with "The Phases of Development of Living Matter," was also published in German in 1873. In it the author showed that what at that time were considered to be phases in the life of the protoplasm, must now be "taken as different phases in the development of living matter, one of which is its reticular arrangement in protoplasm." Observations on the amœba, cartilage, and bone corpuscles, and the blood of the cray-fish, show that *protoplasm exhibits differences according to its age.* The youngest particles are homogeneous lumps, without any reticulum. The first differentiation is an accumulation of liquid in vacuoles; and owing to this accumulation in several closed cavities, "the living matter assumes the shape of a frame-work. The points of intersection of the frame becoming granules, by a rupture of many of the walls of the vacuoles a network is established, which represents a later phase of development of protoplasm." The more coarse and closely set the reticulum, the younger the living matter. The central portion remains homogeneous, next this becomes reticular, and a nucleus is developed, having a small compact centre, the nucleolus. This is a complete "cell." It will be seen that the author adopts a different view of the nature of a "cell" from that which Schwann, Brücke, Max Schultze, and others adopted. The term "cell" should, according to Heitzmann, be abandoned, since this "is composed of innumerable particles of living matter, every one of which is endowed with properties formerly attributed to the cell organism." The original granule is morphologically the simplest appearance. This, by growth and splitting, "results in the appearance of a reticular lump, a rather complicated organism, hitherto called 'protoplasm.'" Are the properties usually ascribed to protoplasm applicable to tissues? There is no such thing as an isolated individual cell in the tissues, since all cells are joined, and the body is "*in toto* an individual." There is no need to claim that it is protoplasm which builds up the animal body, since this same protoplasm is only an advanced stage of development of living matter. The living matter of plants is not materially different, but all cells are uninterruptedly connected by offshoots piercing the cellulose walls. The organism is not a community of "cells," as Virchow formulated, but the body is composed of single parts, materially connected together, and no part is at all autonomous, but all combine to make one individual.

The fifth chapter contains a memoir by Louis Elsberg, on "The Structure of Coloured Corpuscles," which are claimed to be simply detached particles of living matter, reticulated, and possessing no investing membrane, differing from white only by the presence of hæmoglobin. A laboriously compiled historical sketch of the subject is appended. An original memoir by A. W. Johnstone finds a place here, in which it is shown that both red and white corpuscles are developed from adenoid tissue.

The sixth chapter deals with "Tissues in General." Here they are defined as "complex formations of living matter, in a network arrangement." Heitzmann concludes, from laborious investigation, that in no tissue whatever do there exist "cells" as isolated individuals. The whole body is one protoplasmic mass, "in which are embedded a relatively small number of isolated protoplasmic corpuscles (migrating, colourless, and coloured blood corpuscles), and various other non-living substances (glue yielding and mucous substances, fat, pigment granules, &c.)." The use of the term "cell" is objectionable, tending to the erroneous idea, that tissue elements are disconnected, whereas they are continuous. This portion of the work is extremely original, and will repay attentive perusal. Many laborious researches are described, and the author's easy style carries conviction with it. Though the ideas here expressed may not be quite new—they are the author's own—and we are glad to see them published in a collected and continuous form.

The Evolution of Morbid Germs: a Contribution to Transcendental Pathology; by KENNETH W. MILLICAN, B.A. Cantab., M.R.C.S. London: H. K. Lewis, 1883, pp. 107.—It might appear hypercritical to take exception to the title of this volume, but we gather that the position for which the author really contends, is that successive generations of an originally innocent—or, at least, indifferent—*Bacterium* (using this word in its most general sense), acquire morbific properties by virtue of the "struggle for existence" which their residence and propagation within the body of their 'host' implies: so that, in short, a germ—itself devoid of toxic power—introduced into the human body, may, under favourable circumstances, become, in the course of a few weeks, the ancestor of descendants whose operations are displayed in a typical attack of small pox or diphtheria for

example; the particular form of disease being, apparently, determined by the conditions under which the original germ and its offspring find themselves. The hypothesis is thus used to explain the apparent *de novo* origin of already known maladies, and the development of new and aberrant forms; their acquisition of specific characters; their variability in transmission; and the occurrence of 'hybrid' or 'nondescript' cases: while immunity is "supposed to consist in an alteration in the character of the ultimate tissue cells consequent on their supremacy in the struggle with the bacterian invaders;" and indefinite incubation "merely points to variations in the intensity and protractedness of the struggle."

These views are not altogether peculiar to Mr. Millican; at all events, similar suggestions have been already put forward, as he admits, by Prof. Simon, Dr. Sanson, Dr. E. T. Wilson, and others; but, while they are undoubtedly worthy of consideration, they will require, before they can be accepted by the scientifically cautious investigator, evidence more definite and conclusive, as well as more abundant, than that adduced in the work before us. Mr. Millican appears to have been sometimes too ready to accept a single symptom as evidencing the existence of the specific disease in the course of which it does usually appear: and he ignores that mimetic power, for the explanation of which it is by no means requisite to suppose the co-existence of two or more diseases. In the case which he quotes first, and as the one which suggested this enquiry to him—a supposed 'concurrence of typhus and enteric fevers with diphtheria and small pox'—it is remarkable that not only did the patient recover, and that there was, apparently, no albuminuria or subsequent paralysis, but that 'no form of disease was transmitted from this patient to any inmates of the house.' Moreover, having regard to the insanitary conditions discovered by the Medical Officer of Health, and to the patient's occupation—working on the roads—and his admitted 'habit of drinking water out of any of the wayside pools,' is it necessary to view his case as one of "the apparent *de novo* origin of a disease resembling . . . . four commonly supposed distinct 'specific' diseases?" The author seems to ignore the fact that the process of *degradation*, which would itself suffice to explain many apparently anomalous cases of the action of 'disease-germs,' is often equally important with that of development or acquisition of powers in the progress of evolution. In "my own case of evolution of scarlet fever" (p. 81), certain (ancestrally) 'indifferent germs' are considered to have 'acquired specific infectiveness' by the transmission of successive generations through three other children and the mother, who had previously exhibited different combinations of sore throat and diarrhœa with more or less rash and desquamation; the whole period occupied in the process of evolution being some 26 days, equivalent, we are told, to about 1,700 generations of bacteria. The child last attacked seems to have had typical scarlet fever; yet applying this hypothesis to this and similar cases, and having regard to the vast inherent probabilities of variation in development under the circumstances of such *de novo* origin, we should be rather surprised than otherwise to find, as the result of a fortnight's evolution, a disease presenting exactly all the typical peculiarities which are pathognomonic of that well recognised form of scarlatina, whose 'specificity' has (on the same theory) been nurtured, fixed, and strengthened by hereditary transmission through billions upon billions of bacteria generations and several hundreds of patients.

It is almost needless to remark that the author refers all and every disease, or 'departure from the normal line of health,' to bacterial machinations: an hypothesis which, however plausible, has as yet been demonstrated in only two or three instances at most. It is surely more bold than scientific to accept as solid ground, the causative connection between the occurrence of organic forms in the tissues and the existence of "specific" disease, because "this has been abundantly shown in the case of *Bacillus Anthracis* . . . . and *Bacillus Malariæ*," and "micro-organisms have now been more or less definitely connected with relapsing fever, anthrax, elephantiasis . . . . . &c., and other diseases."

On page 91 Mr. Millican quotes, as a footnote, but in apparent continuity with and corroborative of his argument, part of an article on bacteria and disease which appeared in this Journal on November 8, 1883. Taken, however, in conjunction with its context in the original article—in which the writer states, "It must not be supposed that we intend in the above remarks to suggest that one and the same species of harmless bacteria can assume a number of pathogenic phases according to circumstances: that would be carrying hypothesis beyond the limitations accorded by known facts"—it is plain that such a special construction and application of the quotation is scarcely warranted.

There are some theories which, like the theory of gravitation in astronomy and the moleculo-atomic theory in modern chemistry, may be said to depend for proof entirely on the results which their application has enabled scientific workers to achieve. The theory now before us is, to say the least, a plausible one; but it will be more likely to secure general acceptance as a working hypothesis when it is advanced with more deliberation and upon a less dubious basis.

The book is nicely got up, and the interspersion of the text with occasional words and sentences printed in heavy type, though it gives a sensational aspect to the page, and is somewhat trying to the eye, at least possesses the advantage of quickly directing the reader's attention to those points which the author deems of importance. Errors of spelling and of construction—doubtless due to hasty revision—occur here and there; and Mr. Millican appears to be unjust as well as obscure when he states (p. 3) that it was owing to "that very antagonism of authorities of repute, greatly aided by the kindly encouragement and attention of many well qualified to judge on the merits of the question," that he was emboldened to publish his book.

Typhoid Fever in Victoria; by JAMES W. BARRETT, M.B., Ch.B. Melb., Resident Medical Officer to the Melbourne Hospital. Section. I. Melbourne: George Robertson, 1883, pp. 44.—The courtesy of a fair hearing is by long-established custom conceded to the maiden speech of a new member, and in like manner the maiden efforts of a new writer may fairly claim the courtesy of careful perusal and generous criticism. Not only as the first literary venture of its author, but also as the first production of a medical graduate of Melbourne University, the work before us deserves attention. The subject is one with which the author, from his official position, is peculiarly well qualified to deal. Typhoid fever appears to be almost a scourge in Victoria, especially in the smaller settlements, and in dealing with it, as he proposes to do, in a large work of which the present is only the first section, Dr. Barrett will doubtless "do the State some service." In the commencement of the present section, the author plunges *in medias res* with the proposition that all the forms of continued fever which are prevalent in Victoria are only varieties of typhoid. The simple febricula, or fever, in which no characteristic symptoms are present beyond those of pyrexia, has hitherto been looked upon as a distinct disease. A series of facts and arguments are here adduced to prove the incorrectness of this view. The equal prevalence of the two diseases in particular years and months, the probability of their both being due to a single poison, their equal predisposition to attack females more frequently than males, and their clinical similarity, are severally discussed and supported by strong statistical evidence. A few cases, with temperature charts, are recorded, to emphasise the probability that the two diseases may arise from a common source, and that a mild typhoid may be clincally indistinguishable from a febricula. It will be observed, however, that no definite mention is made of typhus fever, as distinct from typhoid, or of relapsing fever. The sanitary conditions which the author describes in the latter portion of his paper, as existing in so many country districts, are precisely those which are usually associated with the prevalence of typhus, but, if negative evidence may be regarded, we must assume that the latter is unknown in Victoria. Whilst agreeing with the author in the correctness of the deductions which he has drawn from the facts that he brings before us, we must still express a decided feeling that the evidence derived from the clinical history of a few typical cases is hardly sufficient to warrant our acceptance

of so sweeping a proposition as that of the identity of all the forms of continued fever in Victoria. The difficulty of collecting trustworthy information is doubtless far greater in the country districts in Australia than in Europe, and time will enable Dr. Barrett to widen his range of observation as his work progresses.

The greater portion of the present section deals with the ætiology of typhoid fever in Victoria. The following points are each in turn discussed, and statistical tables and charts are appended:—The relation of other diarrhœal affections to typhoid; the seasonal prevalence of the disease; its greater frequency among females; the commonest age for attack; its mortality, causation, and prevention. In Victoria the "typhoid season" lasts from January to May (*i.e.*, during the Australian autumn), and from a study of meteorological records, the author finds the only climatic condition which appears to influence its intensity is the amount of rainfall. The fever is mild in seasons of heavy rains, and more severe in the dry seasons. The mortality, both in Melbourne and in the country districts, appears to be high. In his chapters on the causation and prevention of typhoid, the author writes directly for the information and instruction of his fellow Victorians, and hence adopts a style which will doubtless be well appreciated by those to whom his words are addressed. The facts and instances which he cites are most suggestive and interesting in themselves, although wanting in that absolute accuracy of detail which is essential to scientific investigations at the present time. The earlier chapters of this very concise and instructive paper are written in clear, terse style; indeed, the author almost errs on the side of economy of words; but as they form the first step in a work which we hope to see expanding into a treatise worthy of his university, we may congratulate him on the production of so thoroughly genuine a beginning.

Plant Analysis — Qualitative and Quantitative; by Dr. DRAGENDORFF. Translated by H. G. GREENISH, F.I.C. London: Baillière, Tindall and Cox, 1884.—Scientific men owe a large debt of gratitude to Mr. Greenish for this work, which could hardly have been satisfactorily performed but by one who, like the translator himself, had been a pupil in the author's laboratory. The thoroughness with which he has performed his task may be gathered from the fact that the index is more copious than in the original, having been compiled from the English text. The author lays especial stress in his introduction upon the nature of the solvents employed in extracting the various constituents of plants, the object in view being to employ the simplest solvents possible, so as to avoid any violent action upon the constituent to be dissolved, and to apply the various solvents in such order that the constituents may be *separated* from one another as far as possible by their means. One of the solvents employed and recommended by Professor Dragendorff is "Petroleum Spirit." Now, as this reagent is undoubtedly a good solvent for fatty matters, and is not at present largely employed in this country, it is advisable that it should have a fair trial. It is directed on page 8, that the petroleum spirit should contain no compound boiling above 45° Centigrade. Now the petroleum spirit of the oil-shops contains little of any compound boiling below 50° C., but the chemical manufacturers sell a liquid under the name of "*Petroleum Ether*," of which one-half by volume boils at temperatures below 50° C., which is accordingly available for the purposes of plant analysis.

The first part of the work consists of directions for the complete analysis of a plant by employing the various solvents, viz. petroleum spirit, ether, absolute alcohol, water, dilute soda solution, and dilute hydrochloric acid, in the order indicated, each solvent separating a certain class of compounds. Having regard to the instability of many of the constituents of plants, the author directs that *heat* should not be applied in most cases, in order to accelerate solution. Accordingly we find it commonly stated that several days are to be allowed for the digestion of the plant with a solvent at the ordinary temperature in order to ensure complete extraction, a sacrifice of time which is necessary for the ensurance of scientific accuracy, but which would doubtless be in many cases inconvenient. Those analysts, however, who desire to effect a more rapid examination of a plant for some particular ingredient whose presence they suspect, or whose quantity they wish to estimate, will find their requirements met in the second part of the work, which describes "Special Methods" for the extraction of special constituents, &c.

Valuable tables are distributed through the work, *e.g.*, the behaviour of Vegetable Oils to Reagents, on p. 103, and of Vegetable Alkaloids to Reagents, on pp. 179, 180; and at the close of the work are two particularly useful ones, viz., an alphabetical list of plant constituents, with their formulæ and per-centage compositions attached, and a list of the more important constituents of plants arranged in order according to the percentage of carbon they contain, oxalic acid heading tht list with 26·66 per cent. by weight of carbon, and styrol closing it with 92·31 per cent. of that element. The English chemist and pharmacist cannot fail to benefit from the use of this work, and we thank Mr. Greenish for placing it within their reach.

ABSTRACTS AND EXTRACTS.

OBSTETRICS.

THE VOMITING OF PREGNANCY.

A RECENT number of the *Zeitschrift für Geburtshülfe und Gynäkologie* contains a long and elaborate paper on this symptom, by Dr. M. Horwitz, of St. Petersburg. The gastric disturbances of pregnancy differ widely in degree. The author, in his paper, especially deals with those cases in which the vomiting is bad enough to impair health, and is not checked by any of the ordinary methods of treatment. For such cases he thinks a special designation is required, and he proposes the term "*vomitus gravidarum perniciosus*." This he would define as vomiting which from the beginning affects the general health of the patient, and which gradually increases till it reaches a stage at which food of all kinds, liquid as well as solid, is rejected by the stomach. It is necessary, for the proper understanding of such cases, to compare them with the slighter forms, and this Dr. Horwitz next proceeds to do. It is seldom that pregnancy exists without some vomiting. In his experience Dr. Horwitz has not met with more than ten cases in which it was absent. It is not possible to lay down any general law as to the precise period of gestation at which it begins. On this point the statements of women of the upper classes, who have more leisure to observe their symptoms, are, our author thinks, more to be trusted than those derived from the lower orders. Dr. Horwitz, therefore, adduces figures from his private practice to show the period at which the vomiting of pregnancy first commenced. Of 186 cases, it began between the fifth and sixth week in 16 cases; the sixth and eighth in 38, the eighth and tenth in 43, the tenth and eleventh in 60, the eleventh and twelfth in 22; in the seventh month in two cases; near the end and very slightly in five cases. He has not been able to find in literature any precise data from which to form an opinion upon the point, and hence the compilation and publication of the table we have quoted. It is seldom that the vomiting begins suddenly; nausea and other symptoms of gastric disturbance generally precede it. These, in the majority of cases, begin in about the fourth week after impregnation, and gradually increase in severity until regular vomiting sets in about the tenth week. The longer the preliminary nausea lasts, the shorter is likely to be the duration of the vomiting. The vomiting of pregnancy differs from that due to disease of the stomach in that it is not preceded by pain, nor immediately by nausea, and that the vomited matter does not contain undigested food, but consists only of mucus, which is occasionally tinged with bile. The foregoing remarks apply to the ordinary slight vomiting which occurs in the majority of pregnancies. We now come to the more distressing cases in which treatment is required. The pernicious vomiting, to use the name which our author

gives it, may be divided into two stages, or the cases of it into two classes. In the first, the preliminary nausea is of short duration; the vomiting quickly comes on, and progressively increases in severity, but is not very grievous, because there are considerable intervals between the attacks and it does not disturb the patient at night, and the appetite, although diminished, is not quite absent. In this stage the malady cannot be considered dangerous, although it is troublesome. Dr. Horwitz has observed a symptom present in this stage which has as yet not been described, viz., increased sensitiveness of the sense of smell ("hyperosmia"). The patient complains of a disagreeable odour, which she may attribute to something in her surroundings or to the emanations from her own body, and which provokes nausea. It is very troublesome, cannot be removed by treatment, but fortunately is only periodic in its presence, and does not remain long. Dr. Horwitz considers it an important symptom, from the point of view of prognosis. In the second stage, the symptoms become serious. The attacks of vomiting become more frequent, till it at length becomes almost incessant. The straining is excessive and exhausts the patient. Neither food nor drink can be retained, and the vomiting prevents the patient from getting rest at night. The vomited matters begin to now and again contain blood. The tongue becomes red, the gums dark; the urine becomes scanty, and often albuminous. Dr. Horwitz has noticed a relation between the diminution in the quantity of urine excreted, and the severity of the vomiting. It is commonly stated that in these severe cases a febrile condition comes on. This Dr. Horwitz has not been able to confirm. He doubts its accuracy the more, because those authors who make it do not quote thermometric observations in support of their view. In the first stage of the affection the temperature is normal, and in the second stage only so slightly and irregularly raised that no definite febrile type can be described, and often it is subnormal. Where the temperature is high, Dr. Horwitz suspects the presence of some undetected complication. The pulse becomes rapid, small, compressible, and easily accelerated. The patient rapidly wastes and loses strength, but the cerebral functions remain unaffected, except that during the two or three days preceding death there may be transient delirium. Studying these bad cases still more closely, Dr. Horwitz finds that their progress may be further subdivided into three stages. In the first of these there is evident wasting, urgent thirst, loathing of food, although often the patient will crave for, take, and retain aliments of the least digestible kind, while foods apparently more suitable will be at once rejected. There is epigastric pain and tenderness. Sleep is prevented by the vomiting. From this condition it is possible that the patient may recover. In the second stage the symptoms just described are present in greater intensity. Slight elevation of temperature towards evening sets in, and the pulse rises to 120° or thereabouts. The breath becomes fœtid, the tongue dry and dark, the buccal mucous membrane sore. The epigastric pain is continuous. The patient lies in bed with her knees drawn up, apathetic, showing no interest in anything about her. In the third stage sensory disturbances, hallucinations, delirium, faintings, come on. The pulse is scarcely perceptible, hiccough may appear, and finally a comatose condition ends the patient's sufferings. These symptoms are those simply of death from starvation. Dr. Horwitz compares them with those observed in dogs experimentally killed by starvation, and shows that the essential phenomena are identical in their course and nature. Having thus described the disease, our author next considers its ætiology and pathogenesis, questions concerning which, as he remarks, many and widely differing opinions have been held. He believes that vomiting of pregnancy of the severest kind is met with more among women of the upper classes than among those of the lower, and that it occurs with different frequency in different races, being rare in Germany, less seldom in England, more frequent in France than in either. Thus he has himself only seen two fatal cases; Hohl states that he has never seen a fatal case; while Paul Dubois has observed twenty. Dr. Horwitz is inclined to think with the majority, although cases collected by Rosenthal seem to show the contrary, that it is more common in first than in later pregnancies. He holds that we are justified in regarding the symptoms as a reflex phenomenon. The precise mode in which the reflex irritation comes about is hard to explain. Tyler Smith and Schröder have attributed it to distension and stretching of the uterus; but this is hardly consonant with the fact that the vomiting commonly comes on when the expansion of the cavity is slight, and ceases before it becomes great. Dr. Graily Hewitt's theory, that it is due, like most other derangements of females, to flexion, is rejected *in toto* by our author, on the grounds that we often see severe vomiting when the uterus is perfectly straight, and acute flexion without any sickness at all. He adds, "the epoch in gynæcology in which versions and flexions of the uterus were regarded as in themselves something very serious and pathological, is long gone by." He is in accord with Dr. Henry Bennet in thinking that many cases of severe vomiting of pregnancy depend upon inflammatory conditions of the uterus; but he differs from him in that he regards chronic inflammation of the body of the uterus as being of much more importance than erosion of the cervix. The latter condition, he points out, is extremely common, and he holds it to be of no consequence. In many cases of severe vomiting he has found the uterus larger than it should be, very tender, and less movable than natural; and these he regards as indications of an inflammatory condition of the body of the uterus. Perimetritis may also be the cause of very severe sickness. Some of the worst cases of pernicious vomiting depend on morbid conditions of the stomach, the reflex irritation which the pregnant uterus causes in the healthy stomach, being enormously increased when that organ is diseased. An unhealthy condition of any part of the alimentary canal will increase the severity, and the difficulty of repressing, the vomiting of pregnancy. In order that it may be efficiently treated, it is obviously necessary that a correct diagnosis should be made, and any of these adventitious conditions recognised if present. The prognosis largely depends upon the period of pregnancy at which the vomiting becomes pernicious. The earlier it reaches this degree, the graver is the outlook. The signs which indicate an approaching unfavourable termination are—the progressive diminution of the amount of urine passed, and the presence of albumen in it; dusky tongue; severe headache; small and rapid pulse; and, finally, an apathetic state of the patient. Lastly, we come to treatment. A legion of drugs have been recommended for the symptom under discussion; but as a case which yields to drug treatment cannot be called pernicious, their detailed consideration is outside the subject of this paper. The patient should be kept on her back, moving as little as possible, and the room should be darkened. The diet should be confined to articles of the most easily digested kind; but if the patient should wish for things not coming under such a rule, her cravings should be gratified. Bismuth, sucking ice, and counter-irritation to the epigastrium, are the most reliable means of checking gastric irritability. If these fail, and the patient can keep down no food, then we must resort to feeding *per rectum*—a means by which it is indubitable that life can be sustained. A beef and pancreas solution (three parts, by weight, of beef, one part of pancreas, to be chopped up finely, and triturated with two parts of water until a kind of pap is formed), forms the best nutrient enema. In administering these, the following precautions should be observed. The rectum should be emptied an hour or two before injecting nutriment. Too much should not be given at one time; three or four ounces are quite enough; and they should not be given so often as to irritate the bowel. If the patient be very weak, two or three teaspoonfuls of wine should be added to each enema. If the enemata are not well retained, a few drops of Tr. Opii should be given with each. The application of nitrate of silver to an erosion of the cervix, if this be present, Dr. Horwitz thinks advisable; but he regards this measure as simply one of the means of curing inflammation of the cervix, not as a specific for the vomiting of pregnancy. He disapproves of the use of pessaries, preferring to correct displacements by the use of sponge vaginal plugs. His own experience of the effect of Copeman's method, viz., dilatation of the cervix, would make him regard it as almost

useless; but on account of the warm praise lavished upon it by others, he thinks it worth trial. The last resource is the induction of abortion. There is abundant evidence, that often cessation of the vomiting follows the death of the fœtus, before abortion has taken place. Published statistics show a good percentage of cessation of the vomiting and recovery in cases treated by the induction of abortion; and that this has not been the case in a larger proportion, Dr. Horwitz thinks, is because it has too often not been done until the patient was in a hopeless condition. If done, it should not be postponed till the patient reaches this point. The means which our author prefers is the warm vaginal douche, followed by the dilatation of the cervix with tents. If this has not been done soon enough to give the patient a chance of recovery by the natural powers, one last means may be recommended to avert impending death, viz., transfusion. Dr. Horwitz, however, cannot say that he knows of, or has read of, a case of the kind in which this measure was of appreciable service.

The Castration of Women.—A recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie* contains an article by Dr Wilhelm Tauffer, of Buda-Pesth, on the above subject. He relates twelve cases of this operation performed by himself, and then presents the conclusions which follow. We cannot say that this author is as cautious in drawing inferences as we should like, but we give his propositions, which must be taken for what they are worth. (1.) Castration is an operation which with proper care is not attended with any great risk: the unavoidable mortality being now less than 10 per cent. (2.) The operation should be performed with antiseptic precautions and under carbolic spray; the abdominal cavity should be closed; drainage is only exceptionally required. (3.) The limitation, that castration is not called for when the climacteric is near, can only be conditionally accepted, because the age at which the climacteric occurs is very different in different individuals, and cannot be foretold. (4.) The condition laid down by Hegar, that the ovaries should be distinctly felt before their extirpation is attempted, is an impracticable one. (5.) Both ovaries should be removed, even if the disease be limited to one; excepting in cases where special circumstances make it desirable to leave behind the apparently healthy ovary. The reason for removing both ovaries is, that the remaining gland has a tendency to become diseased in the same way as its fellow. (6.) It is generally desirable to remove the tubes as well as the ovaries; and it is unconditionally necessary if there be the slightest appearance of disease in them. (7.) Hystero-epilepsy is curable by castration. (8.) The symptoms grouped together under the name of hysteria, when rightly analysed, can often be traced back to ovarian disease. (9.) The question as to the influence upon uterine fibroids of the ligature of large nutrient vessels going to them, without castration, is worth consideration. (10.) With regard to prognosis it is important to remember that the menopause only follows immediately upon the operation in those cases in which the neighbouring organs are not diseased; but all inflammatory conditions of them delay the climacteric. (11.) The final result of castration can only be determined after the lapse of months. (12.) It must be regarded as an open question how far diseases of the female sexual organs influence the development of certain psychoses. (13.) So must the question whether such psychoses are curable by castration. (14.) In the interest of unity and comparison of observations, it is desirable that the classification of cases (suitable for this operation) adopted by Hegar should be generally accepted.

The Dangers of Post-Partum Injections.—Dr. Simon Baruch, in the *New York Medical Journal*, January 5th, 1884, raises a plea against vaginal injections after normal labour. Referring to recent German correspondence on this point, he shows that a reaction against active antiseptic irrigation after labour has already set in abroad; and the fact that the frequent and probably clumsy introduction of the syringe-point (besides conveying sepsis) may itself produce fever, is emphasized in a recent paper by Kehrer ("Archiv für Gynäkologie," 1883). In the utero-vaginal tract after labour, there is, indeed, traumatism; yet it is not artificially, but naturally induced in a physiological process; and instead of a large percentage of deaths, as in the case of serious surgical operations (to which Dr. Thomas would liken the case of a woman in labour), there exists but a very small percentage of mortality or failure. Thus, Runge (who resorts to injections only where there is evidence of decomposition of the lochia), reports 1,500 cases treated expectantly, with a mortality of only 0·39 per cent. from sepsis, and this at a time when puerperal fever was supposed to be epidemic. Fischel reports 993 labours, with a mortality of 0·21 per cent.; and Fehling records, in 1879, 415 cases of labour, with no death from sepsis, although not a single irrigation was resorted to. Dr. Baruch pleads for "simple cleanliness on the part of the physician and nurse, before, during, and after labour," as the best of all prophylactic antiseptics; and quotes Briesky, who maintains that in normal labour Spiegelberg's "in Ruhe lassen" of the puerperal genitalia should be the rule. In his own practice he reports 900 cases of labour, in which almost every known complication was encountered, treated without any prophylactic measures, other than strict cleanliness, "with the result of only one death from a fever process."

PHARMACOLOGY AND THERAPEUTICS.

Refusion in Carbonic Oxide Poisoning.—In the *New York Medical Journal*, December 8th, 1883, Dr. W. S. Halsted, discusses this method of treating cases when death is imminent from inhalation of carbonic oxide or of illuminating gas. The practice consists in removing a quantity of the vitiated blood, and, after defibrination and oxidation, restoring it to the circulation; it is an infusion of pure, defibrinated blood in exchange for the individual's poisoned, entire blood. The good effects of venesection alone, in such cases, have been established by observation and by experiments on animals; why then, it might be asked, transfuse—if venesection accomplishes so much? If for no other reason, the author replies, in order to allow of repeated venesection: the poisoned individual should be bled freely, even after immediate danger seems to be over. Although bleeding of itself will probably suffice to save life in almost all cases which occur in practice, Kühne has shown that poisoned animals, beyond hope of rescue by venesection, can be saved by transfusion; in one instance, where respiration had been suspended for seven minutes, he was able to restore life to the animal by the infusion of defibrinated blood. The theory that the success of infusion depends on the substitution of corpuscles capable of carrying oxygen for those so vitiated as to be unable to perform this function, is negatived by the fact that saline injections are as efficacious as whole or defibrinated blood. As regards the various means by which the blood may be introduced, centrifugal venous infusion is at once rejected; so is centrifugal arterial injection, in view of cases of gangrene so caused, and of rupture of capillaries, owing to the force requisite for overcoming the vascular spasm. Of the two remaining possibilities, centripetal arterial is preferable to centripetal venous injection, because by the former method blood courses more slowly and equally to the heart; because the minutest airbubble is retained in the capillaries; and because the danger of phlebitis is avoided; moreover, arterial blood is thus most directly despatched to the nerve-centres, whence their venous blood is propelled onwards into the veins, and the filling of the arterial system rejuvenates the circulation by creating a considerable difference between the pressures in the two systems. The author's practical results confirm these theoretical advantages. The details are given of two cases successfully treated in this manner.

Danger of Large Doses of Quinine.—Professor A. A. Smith, in a paper read before the New York Clinical Society (*New York Medical Journal*, February 2nd), drew attention to the danger which may accrue sometimes from the administration of very large doses of quinine (30 to 60 grains) for the diminution of temperature in the state of

hyperpyrexia. His own observations have led him to the following conclusions: (1.) "Large doses of quinine should not be given in any case of high temperature after heart failure begins, unless agents to counteract their effect on the heart are given. (Almost any of the cardiac stimulants will aid in counteracting the effect of these large doses, but they should be given every two or three hours, and kept up even after the effect of the quinine has passed off. Small doses of opium best answer the purpose. In doses of a quarter to half a grain it is a cardiac stimulant, besides being, under conditions of high temperature, a great sedative to the nerve-perturbation which accompanies such condition). (2.) Great caution should be exercised in any case of organic disease with enfeebled power, and when used for old people with high temperature." "I am well aware," he says, "of the popular prejudice against quinine, and have hesitated somewhat in calling attention to some of the points involved in this question, because there are so many conditions which can be relieved by quinine better than by any other agent. Indeed, I place it second in importance only to opium in the treatment of disease in this region."

Compression of the Carotids, Combined with Electrisation of the Vagi and Sympathetic.—In the *New York Medical Journal*, February 23rd, Dr. J. L. Corning describes an instrument adapted for this purpose. In shape it resembles the letter Y; the extremities of the two arms can be accurately separated or approximated by the action of a milled head in the handle. To the extremity of each arm a small sponge electrode can be attached, when it is desired to employ electric stimulation in addition to compression; the two conducting cords from the electrodes unite in one common stem, so that the polarity of both electrodes is the same, the other end of the stem being attached to one pole (usually the negative) of a galvanic or Faradic apparatus. The electrodes can be fixed at any desired angle, and the carotids can thus be compressed obliquely, towards the spinal column, and away from the jugulars, thus reducing venous pressure to a minimum. The other pole of the electric apparatus is connected with a curved metallic plate which is applied over the back of the neck. Compression should be carefully regulated, with the view of avoiding dizziness or syncope; and the greater the amount of compression, the less should be the strength of the current, and *vice versâ*; sudden variations in either of these factors are to be carefully avoided. Thus used, the instrument is capable of effecting (1) diminution of the amount and pressure of the cortical blood stream; (2) contraction of the cerebral capillaries; and (3) retardation of the heart's action (*when currents of considerable strength are employed*). Dr. Corning also believes, as the result of experiment, that a *direct* limitation of the processes of intra-cellular activity is attained. In "congestive headache" (angio-paralytic migraine), "its effects are positively magical," such attacks being often cured in a few moments. Dr. Corning finds it of value in epilepsy, and anticipates good results from its employment in the first stages of general paralysis of the insane. He states that the primary stage of excitement incident to etherisation is cut short by resort to this method, and the amount of anæsthetic required is proportionately reduced. Preference is given to the constant galvanic current.

Veratria in the Pruritus of Women.—All acquainted with the incessant suffering which some women undergo from pruritus at the period of the menopause, must be very desirous of being made acquainted with a prompt remedy for so distressing an affection. Whether it arise from the presence of prurigo, urticaria, eczema, herpes, or whether it exist without any eruption at all, it is alike difficult to allay, as the great number of remedies which have been proposed testifies. Of these veratria is by far the most efficacious. When the pruritus is localised at the groins, arm-pits, walls of the abdomen, or behind the ears, gentle friction night and morning with an ointment, consisting of thirty parts of lard and a quarter of a part of veratria, usually gives relief. When the pruritus is generalised, the internal administration of the veratria is preferable. Two centigrammes should be made into ten pills with liquorice powder, of which from two to six should be taken daily, either half-an-hour before, or three hours after meals. Only one should be taken at a time, an additional one being given each successive day until the maximum of six (three milligrames) is attained.—Dr. Chèvon, *Le Progrès Médical*, February 23rd.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, April 8th, 1884.

Dr. George Johnson, F.R.S., President, in the Chair.

The Pathology of Myxœdema as illustrated in a Typical Case.

By John Harley, M.D. Lond., F.R.C.P., Lecturer on General Anatomy and Physiology, and Physician to St. Thomas's Hospital.

The author gave the history of a typical case which was under his care at St. Thomas's Hospital for a period of nearly seven years. The *post-mortem* examination revealed extensive adhesions and thickening of the pleuræ with fibrous degeneration of one lung, and also traces of general peritonæal inflammation, the result of a severe illness after the birth of the patient's last child, ten years before her death. The thoracic ganglia were deeply implicated in the adherent and degenerated pleuræ, and on the left side the ganglia could not be satisfactorily distinguished. Apart from these morbid changes, two main facts were obvious. Firstly, the quantity of blood was small: although the heart was contracted and empty, and one lung degenerated and much less vascular than the normal organ, there was no noticeable fulness either of the superficial veins during life or of the great internal veins after death. Secondly, all the tissues were abnormally firm and tough:—there was a general increase of connective tissue throughout the body. The amount of mucin contained in the more important tissues and organs was determined. The author was not aware that the proportions of mucin, and the other constituents of healthy tissues of various ages, had been ascertained, and he had, therefore, determined this question in respect of another patient, a woman, aged twenty-four, who died of mitral disease. On comparing the analyses in the two cases, it appeared that the quantity of mucin was nearly doubled in the myxœdemic case. The author, however, hesitated to conclude from such scanty evidence that the mucin was in excess of the normal amount. But he thought that the question of an increase of mucin sank into insignificance in face of the unmistakably great increase of connective or fibrous tissue, and to which the increase of mucin, if this should be constantly demonstrated, might be regarded as secondary. The cerebro-spinal nervous system was evidently very slightly affected, but the sympathetic was in many cases more deeply involved. He referred to a case of so-called "simple atrophic sclerema," but really one of fibrous degeneration of the lungs and thoracic sympathetic, published in vol. lx, of the "Transactions of the Royal Medical and Chirurgical Society," as illustrating this view. The myxœdemic and scleremic conditions in these patients were merely the consequence of severe internal inflammation, experienced

years before and affecting, *inter alia*, the pleuræ and peritonæum, and the sympathetic ganglia adjacent to these membranes. In the two cases referred to, fibrous degeneration of the lung was a notable factor in the disease, but it was of course conceivable that myxœdema, scleroderma, and its allies might have their origin in inflammatory or other changes exclusively confined to the sympathetic ganglia. If this view of the pathology of the disease should prove correct, myxœdema should not be regarded as a specific disease, but merely as a variety of what the author termed "a chronic cold debility," dependent on depression of the vital functions, and frequently associated with fibroid degeneration of the lungs; a condition, usually, if not always, traceable to some severe antecedent illness attended by internal inflammation.

Dr. Ord did not quite know whether to rejoice or to regret that his former patient, the subject of the paper, had fallen into the hands of his colleague, Dr. Harley. The Society had, however, the advantage of hearing a totally independent view of the disease, and from one, who had apparently kept his mind uninfluenced by any previously expressed views. Under these circumstances, it was pleasing to find that Dr. Harley regarded the disease as a distinct entity. He was obliged to differ in some respects as regards the clinical details, for he still thought the central nervous system suffered; it was not a little remarkable, that many well-marked cases of the disease had been found in lunatic asylums; besides this, distinct histological changes had been found in the nerve tissues. He could not accept the view that the thyroid atrophy was secondary to the disease, he believed it was, on the contrary, an essential element of the disease. He enquired as to the meaning of the term "chronic cold debility."

Dr. Ralfe thought that the author's observations on the lessened quantity of blood, and on the diminution and fluctuation of the urea, both interesting and important. The facts spoke to lessened metabolism, which was taking place in the body generally. He said the increase of connective tissue referred to as being present in the body generally would account for the increased quantity of mucin. There was a parallel disease of the osseous tissue in osteo-malacia, and this, he thought, favoured the idea that the metamorphosis of the tissues was really a reversion to a fœtal type of tissue.

Dr. Duckworth asked the author to briefly state what his views really were concerning the nature of the affection. In his own opinion, the disease was quite distinct as a clinical entity, though its pathology still remained somewhat obscure.

Dr. Hadden expressed his belief that the atrophy or absence of the thyroid was an essential part of the disease.

Dr. Harley replied, after which the Society adjourned.

OBITUARY.

SURGEON-GENERAL CHARLES ARCHER, M.D.

Dr. Archer, late of the Indian Medical Service, well known in Bengal for his profound knowledge and successful treatment of diseases of the eye, died in London, March 17th. Born in 1818, he was a lineal descendant of John Locke, and studied medicine at the Westminster Hospital, under Guthrie and White, with such zeal and success that before he was twenty-one he was placed in charge of the Ophthalmic Hospital, Charing Cross, and became house surgeon of the Westminster. On obtaining the diploma of the Royal College of Surgeons, he entered the Indian Medical Service in 1841, and, after holding several important posts with distinction, he eventually came to Calcutta, where he was appointed Professor of Ophthalmic Surgery at the General Hospital, the Ophthalmic Hospital being also placed under his charge. He acquired a large private practice, but found time to pursue scientific investigations, the results of some of which, on light, appeared in a paper read before the Royal Society. Well known to Lord Elgin, on this nobleman's death, in 1865, he was selected by the Indian Government to accompany Lady Elgin home. In 1868, he became deputy-inspector of hospitals in the North Western Provinces, and latterly in Oude, where he must be well remembered. He retired from the service in 1873; and in 1878, with the permission of the English Government, and at the request of the Dutch Government, he repaired to Java and Sumatra in order to investigate the origin of the cholera that had long decimated the troops at Atchin. This mission was eminently successful. Although Dr. Archer never practised after his retirement, he was always ready to aid those in need of his advice, especially in regard to diseases of the eye, in the treatment of which he was so great a proficient.

GENERAL CORRESPONDENCE.

CREMATION.

[To the Editor of the Medical Times.]

Sir,—In a letter dated 22nd April, 1874, which you kindly published for me from Regent's Park, N.W., I ventured to observe with regard to Cremation, so ably suggested by Sir Henry Thompson, that it did not require deep thought to see in Cremation the forerunner of many a "Lucrezia Borgia." As a *complete safeguard* against this most serious and glaring possibility, I perceive that the Council of a Society, calling itself the Cremation Society of England, have decided "that a certificate must be sent in by one qualified medical man *at least*, who attended the deceased until the time of death, unhesitatingly stating that the cause of death was natural and what that cause was." I fail to see much difference between this certificate and the usual one given by every medical man; yet cases have occurred where exhumation has proved the death *un*natural. We will suppose, for instance, that a man wished to poison his wife by slow poison, and that he managed to pick a quarrel with her usual medical attendant, discharged him, and a week after the wife died, having been seen by another medical man up to the hour of her death, he being under the impression that her case was misunderstood by her usual medical attendant. Again, would there not be considerable touting for names to be placed on the Company's Books for those who *wished* to be cremated? Cremation, in my opinion, can only be justifiable in cases of criminals, and I sincerely hope that, unless a perfect *post-mortem* examination is carried out in *every* other case of death, the Legislature will abolish all attempts at it in this country.

I am, Sir, yours, &c.,
COSMO LOGIE, M.D.,
Deputy-Surgeon-General.

47, *Queensborough Terrace, Bayswater, W.*
April 7th, 1884.

THE PSYCHICAL RESEARCH SOCIETY AND "CLAIRVOYANCE."

[To the Editor of the Medical Times.]

Sir,—I read with much interest the articles on "Mesmerism" which appeared in your paper in the latter part of last year; and was especially struck with the fact that no comment was made by Mr. Gurney on your assertion, dated November 24th, that on a certain occasion last spring, a party of scientific men, invited to the rooms of the Psychical Research Society, came to a definite conclusion as to the nature of the "experiments" shown. No result, you say, was obtained when effectual means were taken to prevent sight and hearing by the subject; and the inference is obvious.

I have but lately heard an account of a *séance* or *séances* of this Society which strongly corroborates the view taken in your columns of the untrustworthiness of the methods of research employed by the investigators. A medical man

was invited to attend a meeting where the phenomena of so-called *clairvoyance* were to be observed. The subject was apparently blindfolded, and, after an alleged operation of "mesmerism," correctly named several cards which were unknown to the assembled company, but were handed to him, and placed by him at some elevation above and some distance from his bandaged eyes. Despite of a somewhat elaborate method of apparently occluding the subject's vision, the medical observer expressed his opinion that the cards could be easily seen by him; and the sceptic was accordingly invited to blindfold the man himself.

He proceeded to place pads of cottonwool in the orbits and to apply a bandage; but was told by the professed mesmerist that the organs by which the subject mentally saw the cards were placed in the forehead, and must not be covered up. He, therefore, endeavoured to observe this "condition," but so applied the cottonwool and the bandage as to be quite satisfied that the subject could not see. *No result whatever was obtained during the rest of the séance.* I cannot doubt that a report of this "blank day" will be given in the *Proceedings* of the Society. But I venture to trouble you with this letter in the belief that it may interest those of your readers who may have followed the recent correspondence on this subject in your columns, and as a not altogether irrelevant comment on Professor Sidgwick's statement not long ago, in a lecture given at the London Institution, that the Psychical Research Society had definitely ascertained certain "facts" hitherto unrecognised by science.

I am, Sir, yours, &c.,

April 8th, 1884. H. B. DONKIN.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.

The ordinary monthly Council was held on Wednesday last. The first business transacted was an address of condolence to Her Majesty the Queen, on the death of H.R.H. the Duke of Albany. Subsequently, a vote of congratulation was agreed upon to the University of Edinburgh on the completion of its three-hundredth year of existence. The President will personally present the vote at the anniversary meeting, when he will officially represent the College on the occasion. The report of the Museum Committee on the duties and emoluments of the new conservator was next considered. As before, the conservator will be the head of the Museum Department, and the salary will be 600*l.* per annum, with residence on College premises. The appointment will be advertised; applications from intending candidates must be in the Secretary's hands not later than May 3rd. The next matter concerned the Secretary. In consideration of his having completed twenty-five years of Service in the College, and in recognition of his arduous labours in connection with the proposed legislative changes, it was proposed that a sum of 500*l.* be presented to Mr. Trimmer, in acknowledgment of his zealous activity in the interests of the College.

The Jacksonian Prize for last year was awarded to Mr. Frederick Treves, F.R.C.S., Assistant Surgeon to the London Hospital, &c., for his essay on the "Pathology, Diagnosis, and Treatment of Obstruction of the Intestines in its various Forms in the Abdominal Cavity." There were only two competitors. The subject for the ensuing year is "Renal Surgery."

A letter was then read from the Home Secretary in answer to a communication made jointly with the College of Physicians concerning the prosecution of Messrs. Bower and Keates. The Home Secretary stated that the advice of the most competent medical men would be sought, so as to prevent any injustice being done to members of the medical profession.

The Report of the General Meeting of the Fellows and Members held on March 24th last was presented. Its further consideration was deferred to the next meeting, which will take place on May 8th.

A letter from Mr. Tweedy, F.R.C.S., calling attention to Section VII., Vict. 15, with regard to members of Council not in actual practice was then read. The letter was referred to the President and Vice-Presidents for consideration. Sir James Paget presented, on behalf of Dr. John Richard Farr, a large and valuable collection of water-colour and other drawings of pathological subjects left by his father, Dr. Arthur Farr.

The Council then adjourned.

Royal College of Surgeons of England.—The following gentlemen passed their primary examinations in anatomy and physiology, at a meeting of the Board of Examiners on the 4th instant, and when eligible, will be admitted to the pass examination, viz.:—Messrs. William H. Tomlinson, C. F. Cheetham, Arthur Greenhalgh, and F. J. Wheeldon, students of the Manchester School of Medicine; A. S. Wilson, E. H. Douty, Thomas Redmayne, and W. K. Sibley, of the Cambridge University; Sargon Fordoff, A. S. Barling, and William Porsitt, of the Leeds School of Medicine; B. G. Sumpter and A. S. Bradbury, of the Newcastle-upon-Tyne School of Medicine; R. J. Mc L. Buchanan, of the Liverpool School of Medicine; A. J. Gorr and G. E. Deacon, of St. Bartholomew's Hospital; Hugh Smith, of the London Hospital; Henry George and S. C. Phillips, of St. Thomas's Hospital; F. W. Fowler, of the Birmingham School of Medicine; H. P. Ziemann, of the Charing Cross Hospital; R. J. Marks and C. E. S. Fleming, of the Bristol School of Medicine. One candidate having failed to acquit himself to the satisfaction of the Board of Examiners, was referred to his anatomical and physiological studies for three months. The following gentlemen passed on the 7th instant, viz.:—Messrs. C. F. Williamson, P. A. Houghton, and W. H. B. Brook, of St. Bartholomew's Hospital; F. W. Abbott and C. P. Oliver, of the Charing Cross Hospital; H. J. Macway, of St. Thomas's Hospital; Arnold Scott and E. R. Davies, of Guy's Hospital; H. W. Dumerque, E. C. Perry, C. W. Daniels, and R. M. Brown, of the University of Cambridge; Eber Candwell and John Watson, of the Westminster Hospital; H. J. Wheeler, of St. George's Hospital; and J. E. Thompson, of the Manchester School. Seven candidates were referred for three months, and one for six months. The following gentlemen passed on the 8th instant, viz.:—Messrs. W. Balgarnie, M. O. Mamson, C. A. Parker, F. G. Engelbach, and O. E. P. Evans, of St. Bartholomew's Hospital; D. Owen and W. P. Stocks, of the Manchester School of Medicine; G. A. Barton, of St. Mary's Hospital; H. Duncan, T. E. Stuart, C. Brown, and H. P. Hawkins, of St. Thomas's Hospital; A. W. F. Noyes, of Charing Cross Hospital; D. J. Mantri, of the London Hospital; H. E. Crook and F. S. Hawkins, of Guy's Hospital. Eight candidates were referred for three months. The following gentlemen passed on the 9th inst., viz.:—R. H. W. Wilbe and K. W. J. Mackenzie, of St. Bartholomew's Hospital; W. F. Clarke, of Guy's Hospital; H. Goodale and N. Lawson, of St. George's Hospital; J. C. Rossall, of St. Mary's Hospital; J. Hamel, C. P. O'Connor, H. P. Dean, and F. G. S. G. Martin, of University College Hospital; R. H. Penton, E. J. A. Haynes, and T. N. Thomas, of London Hospital; G. Barlow, of Manchester; S. W. Wheaton, W. F. Ward, and C. O. Parsons, of St. Thomas's Hospital; G. H. O'Reilly, of King's College Hospital; H. C. Bartlett, of Middlesex Hospital; and C. Scatchard, of Leeds. Two candidates were referred for three months, and one for six months.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, April 3, 1884:—

Cooper, Chas. Bolingbroke, Oakhill Park, Stoneycroft.
Johnson, Obadiah, Hastings, Sierra Leone.
Jones, Thomas, Columbia Road, Hackney Road.
Newton, Sidney Frederick, Long Acre, W.C.
Nunn, John Robert, Repton, Burton-on-Trent.
Swindlehurst, Thos. Newton, Newington Crescent, S.E.
Tovey, Reginald Samuel, Royal York Crescent, Clifton, Bristol.

Naval Medical Service.—The following promotions have been gazetted:—Staff Surgeon William Dudley

Wodsworth, to the rank of Fleet Surgeon in Her Majesty's Fleet. The under-mentioned Surgeons to the rank of Staff Surgeon in Her Majesty's Fleet (dated March 30) :—John William Davis, M.D., Henry Thompson Cox, Cecil Drake, John Wood, Alfred Thomas Corrie, John Mackie, Henry Scanlan, M.B., and Herbert Mandeville Nash.. The following appointments have been announced :—Staff Surgeons—John W. Davis, M.D., to the *Duncan*, additional, for temporary service in lieu of a surgeon ; Henry T. Cox, to the *Cambridge* ; Cecil Drake, to the *Inflexible* ; John Wood, to the *Neptune* ; Henry Scanlan, to the *Belleisle* ; Herbert M. Nash, to the *Lion*. Surgeons—Edgar R. Dimsey, to the *Hercules*, complement incomplete ; Anthony R. Lynch, to Malta Hospital, *vice* Yeo ; Matthew Digan, to the *Sphinx*, *vice* Logan ; Arthur W. Russell, to the *Polyphemus*, *vice* Digan ; Robert F. Yeo, to the *Decoy*, *vice* Lightfoot ; John Wilson, M.D., to Sheerness Dockyard, *vice* Lynch ; James B. Clibborn, to Plymouth Hospital, *vice* Wilson ; James Porter, M.B., to the *Euryalus*, additional, for the Marine Battalion in Egypt ; William Thompson, to the Portsmouth Division of Royal Marines, *vice* Porter.

Royal Institution of Great Britain.—The following arrangements for the lectures after Easter have been announced :—Dr. Klein, two lectures on "The Anatomy of Nerve and Muscle ;" on Tuesdays, April 22 and 29. Professor Gamgee, five lectures on "The Physiology of Nerve and Muscle ;" on Tuesdays, May 6 to June 3. Professor Dewar, M.A., F.R.S., M.R.I., seven lectures on "Flame and Oxidation ;" on Thursdays, April 24 to June 5.

Royal Medical and Chirurgical Society.—The Library of this Society will be closed from Good Friday to Easter Monday, both days inclusive.

Conference on School Hygiene.—The Council of the National Health Society having been invited by the Duke of Buckingham, Chairman of the Executive Committee of the approaching International Health Congress to suggest a subject for a conference to be held at the same time, have determined to hold one on School Hygiene, to which the most eminent authorities on the Continent and in America will be asked to contribute papers on various questions, especially those on which we in England may learn much from our neighbours. The secretary of this conference is Dr. Edward F. Willoughby, who had already acted in the same capacity for the Committee which was appointed by the Society on the subject of the use of poisonous pigments, and which has drafted a Bill for the prohibition and regulation, under certain circumstances, of arsenical colours, based on the laws in force in other countries. Any communications on school hygiene, in every branch, will be thankfully received by him, addressed to the offices of the National Health Society, 44, Berners Street, S.W.

Bristol Royal Infirmary.—The Secretary has favoured us with the following analysis of casualties treated during the year 1883 :—Broken legs 93, arms 64, ankles 57 ; burns 118 ; scalds 124 ; run over 73 ; broken thighs 33 ; injuries to knee 141, eye 219, arm 193, ribs 92, shoulder and back 124, stomach 57, back (alone) 48, thigh 21, mouth 80, face and nose 167, groin 17, chest 9, foot 228, finger 272, hip 23, side 43 ; cut hands, wrists, &c. 437, heads 239, arms 122, lips 123, legs 194, tongue 38 ; crushed hands 90 ; bites by human beings 17, dogs 109, cats 12, monkey 1, horses 7 ; kicked by horses 3 ; needles in hand, &c., 25 ; swallowing pins, coins, &c., 12 ; bones lodged in throat 27 ; falls from scaffolding 13, out of window 3 ; injuries to breast 18 (women) ; foreign bodies lodged in nose, ear, &c., 18 ; cut throats 3 ; kicks in vital parts 5 ; sprains, bruises, wounds, &c. (difficult to classify) 674—total 4,486, being upwards of twelve daily through the year.

The Third Italian Surgical Congress.—It has been decided by the Committee that the third Surgical Congress shall be held at Turin (during the International Exposition), from the 15th to the 20th of September, under the presidency of Professor Battini. Communications, exclusively relating to surgery, instruments, and anatomical, pathological or microscopical preparations, are to be forwarded at least a month before the meeting of the Congress, addressed to the Secretaries, at the Accademia Medica di Torino.

The Police and Ambulance Work.—The Commissioner of Metropolitan Police has forwarded to the Central Executive Committee of the St. John Ambulance Association a report of a most effective case of "first aid to the injured" rendered by Police Constable Thomas Pearson, 112 B, who was awarded a certificate last year after attending the classes at Albany Street Police Station. It appears that a man was found by the Constable in the Buckingham Palace Road, suffering from hæmorrhage, caused by the bursting of a varicose vein. Pearson immediately took the proper measures to arrest the bleeding, and afterwards conveyed the man to the Westminster Hospital, where it was stated that had these precautions not been taken, the man would probably have bled to death, a letter being subsequently received from Dr. Newick, the acting house surgeon, testifying to the opportune good service rendered by Police Constable Pearson, who will be rewarded by the Commissioner. Considering the frequency of accidents in our streets, and that the duty of conveying the unfortunate sufferers to the hospital devolves upon the police, too much praise cannot be accorded to the numerous officers of the force of all grades who voluntarily attend these classes.

School Attendance and Infectious Disease.—A memorial has been drawn up and signed by eighteen medical officers of health in the County Sligo, with reference to the spreading of infectious diseases amongst children attending National Schools. Children, it is stated, are sent to school from homes in which scarlatina, measles, and whooping-cough exist, "thereby making the school a centre of contagion whereby the lives of children from healthy homes are endangered and often sacrificed." It is urged that school teachers do not take means to put a stop to this deplorable evil because it would mean a pecuniary loss to them were the number of attendances lessened, and therefore they do not exercise proper care and circumspection or render any effectual aid in preventing the spread of disease. It is suggested by the memorialists that when any infectious disease breaks out in the district, and is likely to become epidemic, the schools should be closed by the sanitary authority, and the pecuniary loss should be made good to the teachers, by which means their assistance might be calculated on in the important work of the preservation of the public health.

Hospitals at Cairo.—A meeting was recently held to arrange for the amalgamation of Lady Strangford's Hospital with the German Deaconesses' Hospital. Sir Evelyn Baring, who presided, gave a sketch of the history of the Lady Strangford Hospital, and stated the reasons which had now caused it to be closed, winding up with the expression of his hope that all present would heartily support the new German-English Hospital, to which Her Majesty had graciously consented to give the name of the Victoria Hospital. The Egyptian Government promises an annual subsidy of 2,000*l.*, but 1,500*l.* are still needed for opening the new hospital.

Edinburgh Quarterly Health Returns. — The total number of deaths recorded in this city during the past three months was 1,191, giving a death-rate of 19·31 per 1,000 of the estimated population. The zymotic mortality was as follows :—Typhus, 4 ; typhoid, 16 ; diphtheria, 11 ; scarlatina, 34 ; measles, 53 ; whooping-cough, 45 ; erysipelas, 5.

The Vienna Registration Returns for 1882.—The marriages were 6,526 in number. There were 29,262 births (27,857 living and 1,405 dead children), 15,085 being males, and 14,164 females, the sex of 13 fœtuses not being discernible. There were 16,605 of the number legitimate, and 12,657 illegitimate, the percentage of illegitimate births having fallen from 45·2 in 1881 to 43·2 in 1882. There were but 39·5 births per 1,000 in place of 41·7 in 1881. The deaths amounted to 21,595, or 29·2 per 1,000. In March the highest, and in September the lowest, mortality occurred. A fourth of the entire number of deaths arose from tuberculosis.

THE PHYLLOXERA IN 1883.—At the last meeting of the Phylloxera Commission it was announced that none of the procedures proposed for the extermination of this pest of the vine during 1883 offered any hopes whatever of success; and that the prize of 300,000 francs offered, by the law passed, as long ago as 1874, to the author of an efficacious and practical remedy, cannot be awarded. The commission, therefore, recommends the continuance of the employment of submersion, the bisulphide of carbon, and the sulphocarbonate of potassium. "It has observed with the greatest satisfaction that the defence and reconstitution of the vines are more and more developed every year, giving rise to the best hopes for the future."—*Revue Scientifique*, March 8th.

THE BENGAL CENSUS OF 1881.—The *Indian Medical Gazette* for February supplies an interesting analysis of the census returns for Bengal, taken in 1881. The total population was found to be 69,536,861, viz., 34,625,591 males, and 34,911,270 females. The average density of population, was 371 per square mile, or excluding Feudatory States, 442. The province is the most densely peopled of all Indian provinces, and is not far behind Belgium with its 486 and England and Wales with 445. Different parts of the province vary greatly in populousness, the density of the Feudatory States being but 77, while that of Bengal proper is 505. The most populous district is Howrah, with 1,027 inhabitants to the square mile. But Bengal differs widely from European countries in the small proportion of its urban population, which consists only of 5·26 per cent. of the whole population—this being in England 66 6, in France 36·6, and in the United States 22·5 per cent. Bengal is, in fact, a country of villages, and large towns are few in number, and not very populous. Compared with 1872, the population has increased by 10·89—part of such increase being due to improved enumeration. Of the entire population, 65·56 are Hindoos, 31·21 Mahomedans, 18 per cent. Christians, and 0 22 are Buddhists, and other religions 3·01. Almost the whole of the female population becomes married before the age of 20; and between the ages of 30 and 39 there are 90·23 of the whole male population married. While the great majority of girls marry before the age of 15, only one-fifth of the boys are married at that age, and only one-fifth are married before they are 20. Statistics were collected regarding four kinds of infirmity, viz., insanity, from which 4·43 per 10,000 suffered (in England 30·39); blindness, 14·03 (in England 9·51); deaf-mutism, 12·32 (in England 5·07), and leprosy, 8·15.

DEATH OF DR. CHARLES WILSON, OF EDINBURGH.—Charles Wilson, M.D., F.R.C.P. Ed, whose death was recently announced, was born in 1804, graduated at Edinburgh, subsequently studied at Paris, and practised at Kelso from 1828 to 1854. Then after visiting the Medical School of Vienna, he settled down in Edinburgh and continued to practise till 1864, when he retired. He was mainly instrumental in founding the Edinburgh Sick Children's Hospital, and was for several years honorary librarian to the College of Physicians. In 1855, Dr. Wilson published a work on the "Pathology of Drunkenness," and among his contributions to medical journals were articles on "Croup," and on the "History of Medicine in Spain."

DEATH OF MRS. HANCOCK.—The death is announced of Mrs. Hancock, the widow of Mr. Henry Hancock, Surgeon to the Charing Cross Hospital, and formerly President of the Royal College of Surgeons; she died at the Palace, Gibraltar, the residence of her son, Sir. H. Burford Hancock, on the 27th ultimo.

CHARITABLE BEQUESTS.—Mrs. Mary Tait, late of York Terrace, Regent's Park, has bequeathed under the name of "The Carlyle Bequest," 2,000*l.* each to the Royal Infirmary Lunatic Asylum and Lock Hospital; the Northern Hospital; the Southern Hospital; the North, South, and East Dispensaries; the Infirmary for Children; the Hospital for Consumption and Diseases of the Chest, Brompton; St. George's Hospital, Hyde Park Corner; St. Mary's Hospital, Paddington, and the Birkenhead Hospital; 1,000*l.* each to the Bootle Borough Hospital, the Consumption Hospital, Liverpool, and the Eye and Ear Infirmary, Liverpool.

ABSENCE OF THE KIDNEYS AND UTERUS.—It may interest some of our readers to be made aware that Dr. Edmondo Coen, assistant pathologist in the University of Bologna, furnishes, in the *Annali Universali di Medicina*, for January, a minute anatomical description, illustrated by figures, of a fœtus without kidneys or uterus. The paper is far too long to admit of insertion in our pages.

HYDROPHOBIA.—An inquest was held on Saturday at St. Bartholomew's Hospital on the body of a young man, who had died of hydrophobia a month after being bitten by a cat.

ADULTERATED BUTTER IN AMERICA.—The *New York Medical Record* of March 8th states, "The Senate committee have been investigating the subject of adulteration of butter with interesting results. About a million and a half pounds of imitation butter is annually sent into New York, a large part of it coming from the West. Two-thirds of the ordinary butter of the grocers is imitation. Butterine is made from lard and butter, coloured with annatto, and subjected to certain processes of melting and cooling, by which the ingredients are amalgamated. Oleomargarine, which is more notorious in the market than any other of imitation butter, is made from beef fat by various processes, the secret of each being carefully guarded as a trade receipt, although the general features of the rendering are well known. These imitations, when carefully made, are harmless, but they ought to be made under official inspection."

AT a meeting of the Surrey magistrates on April 8th, reports were presented by the visiting justices of the three county lunatic asylums with respect to the management of these institutions during the past quarter. At Wandsworth the number of inmates on the 15th ultimo was 1,016, showing a decrease of 26. At Brookwood there were 1,041 inmates, being a decrease of 29. At the new asylum at Canehill the number of inmates was 1,591, an increase of 511 during the quarter.

CORRIGENDA.—In the paper by Dr. Campbell Brown, and Mr. Davies, published in the last issue of the *Medical Times*, we have to note the following four corrections:—p. 451, first column, fourth line from bottom, for twelve read eighteen; p. 451, second column, thirteenth line from top, for 0·3 read 1·03; same column, twenty-fifth line from top, for 1 grain read 1·1 grain; same column, nineteenth line from bottom, for 1st read 6th.

APPOINTMENTS.

BLACK, R., M.D., M.R.C.S., L.S.A.—House Surgeon to the Sussex County Hospital, *vice* Bernard Scott, retired.

BUXTON, D. W., M.D., B.S., M.R.C.P.—Administrator of Anæsthetics to the Hospital for Women, Soho-square, *vice* T. Bird, Esq.

EDIS, ARTHUR W., M.D. Lond., F.R.C.P.—Obstetric Physician to the Middlesex Hospital, *vice* John Hall Davis, M.D., deceased.

HARRIES, A. J., M.D., &c.—Assistant Surgeon to St. John's Hospital for Diseases of the Skin.

HASLAM, GEORGE JAMES, M.D.—Honorary Physician to the Hulme Dispensary, Manchester, *vice* George Bowman, M.D., resigned.

KEBBELL, C., M.R.C.S., L.S.A.—Junior House Surgeon to the Sussex County Hospital, *vice* R. Black.

PALMER, J. F., L.R.C.P., M.R.C.S.—Assistant Surgeon to St. John's Hospital for Diseases of the Skin.

POWELL, J. J., M.R.C.S.—House Physician to University College Hospital, late Obstetric Assistant to the same Institution.

STARTIN, JAMES, Honorary Surgeon and Lecturer to St. John's Hospital for Diseases of the Skin, Leicester Square, London.—Honorary Consulting Surgeon to the Sheffield Public Hospital for Diseases of the Skin.

VACANCIES.

BIRMINGHAM GENERAL HOSPITAL.—Resident Surgical Officer, &c. *(For particulars see Advertisement.)*

CARLISLE DISPENSARY.—Junior House Surgeon. Salary, £100 per annum, with apartments (not board). Applications, stating age and qualifications, to be sent to the Hon. Secretary, Mr. John Ostell, 14, Bank Street, Carlisle, on or before April 15th.

DURHAM COUNTY HOSPITAL.—House Surgeon. Salary, £100 per annum, with furnished rooms, coals, and gas. Candidates' names must appear on the Medical Register, as being possessed of a Medical and Surgical Qualification, and they must produce evidence of good moral character. Private practice prohibited. Applications, with testimonials, to be sent to the Honorary Secretary, 10, South Bailey, Durham, on or before April 15th.

FLINTSHIRE DISPENSARY.—House Surgeon. Salary, £100 per annum, with furnished house, &c. Candidates' names must appear on the Medical Register, as being possessed of Medical and Surgical qualifications, and they must produce evidence of good moral character. Private practice prohibited. Candidates conversant with the Welsh language preferred. Applications, with testimonials, to be sent to the Secretary, on or before April 15th. The election will take place on April 30th.

DEATHS.

BEST, H. D., M.R.C.S., J.P., at Bilston, on April 6th, aged 51.
CROWN, J. W., M.B., at Terowie, South Australia, on April 4th, in his 33rd year.
NIVEN, D. G., F.R.C.S., at Udny House, Teddington, on April 6th, aged 72.

NOTES, QUERIES, AND REPLIES.

VEGETARIANISM.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—May I ask through your columns for information regarding the cure of disease by means of a non-flesh diet? Will my brother practitioners who have received any benefit themselves from the disuse of flesh, or who have seen cases recover by the disuse of flesh, kindly send me an account of such? Or if any have seen disease produced by the adoption of a vegetarian diet, will they kindly give me an account of it? Any other facts or observations regarding food, will be thankfully received.

I am, Sir, yours, &c.,
T. R. ALLINSON, L.R.C.P. Edin., &c.,

34, *Claremont Square, N.*,
April 8th, 1884.

COMMUNICATIONS RECEIVED—

Dr. T. H. WILLIAMS, Denbigh; Sir EDMUND LECHMERE; Dr. REDWOOD, London; Messrs. LEBON & Co., London; Mr. W. J. WALSHAM, London; Dr. ACLAND, C.B., Oxford; Mr. H. W. GELL, London; Dr. COLLINGRIDGE, London; THE REGISTRAR, GENERAL MEDICAL COUNCIL, London; Mr. HOBSON, London; Mr. DIXON, Dorking; Dr. HERMAN, London; Surgeon-General LOGIE, M.D., London; THE SECRETARY, APOTHECARIES' SOCIETY, London; Mr. J. H. WILLIAMS, Denbigh; Dr. CLIFFORD ALLBUTT, Leeds; Dr. DONKIN, London; Dr. EARDLEY WILMOT, Leamington; Mr. G. F. CHAMBERS, London; THE SANITARY COMMISSIONER FOR THE PUNJAB, Lahore; Mr. A. S. KENNY, London; Dr. EDIS, London; Mr. T. R. ALLINSON, London; THE HON. SECRETARY, PATHOLOGICAL SOCIETY OF LONDON; THE REGISTRAR-GENERAL, Edinburgh; THE COMMITTEE OF THE MANCHESTER AND SALFORD SANITARY ASSOCIATION; Mr. T. M. STONE, Wimbledon; THE SECRETARY, DEVONSHIRE HOSPITAL, Buxton; Mr. DAVIES, Liverpool; THE EDITOR, BRITISH MEDICAL JOURNAL, London; THE SECRETARY, ROYAL MEDICAL AND CHIRURGICAL SOCIETY, London.

BOOKS RECEIVED—

Aural Complications of Inflammatory Conditions of the Nose and Throat, by Beverley Robinson, M.D.—Report on the Derbyshire County Lunatic Asylum—On the Treatment of Spinal Curvatures, by H. Macnaughton Jones, M.D., &c.—Ambulance Handbook, by J. A. Raye, L.K. and Q.C.P.I., &c.—Transactions of the National Association for the Promotion of Social Science—On the Use of Alcohol in Hospitals—Lecture on the Isle of Man, by Alfred Haviland—Vivisection, by E. D. Girdlestone, B.A.—The Contagious Diseases Act—Sessional Proceedings of the National Association for the Promotion of Social Science—Hints on Sanitary Law, by G. F. Chambers, F.R.A.S.—Memoirs of Charles J. B. Williams, M.D., F.R.S.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Revista de Medicina—Bulletin de l'Académie de Médecine—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Revue Médicale—Gazette Hebdomadaire—Nature—Boston Medical and Surgical Journal—Louisville Medical News—Centralblatt für Gynakologie—Le Concours Médical—Centralblatt für Klinische Medicin—Philadelphia Medical News—Le Progrès Médical—New York Medical Journal—Students' Journal and Hospital Gazette—New York Medical Record—The Edinburgh Clinical and Pathological Journal—The Philadelphia Medical Times—Centralblatt für die Medicinischen Wissenschaften—Berliner Klinische Wochenschrift—The Planet—Weekblad—El Ensayo Medico—Journal of Cutaneous and Venereal Diseases—Maryland Medical Journal—The Australian Medical Journal—Popular Science News—The Indian Medical Gazette—The Western Medical Reporter.

APPOINTMENTS FOR THE WEEK.

April 12. *Saturday* (*this day*).

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

14. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

15. *Tuesday.*

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 p.m.—The following Papers will be read:—Dr. Turner, "Cirrhosis of the Liver;" Dr. Cayley, "Abscess of the Brain;" Dr. Semple, "Carcinoma of the Larynx;" Mr. Lockwood, "A Stomach constricted in two places;" Dr. Hale White, "Hour-Glass Contraction of Stomach" (card); Dr. Sharkey, "Multiple Strictures of the Small Intestine;" Dr. Powell, "Duodenal Ulcer with Hepatic Abscess;" Dr. Turner, "Duodenal Ulcer" (card); Mr. Davies-Colley, "Congenital Tumour of Back;" Dr. Carrington, "Cancer of Gall Bladder" (card); Mr. Sutton, (1) "Dissection of Stump" (card), (2) "Separation of Epiphysis of Fibula" (card); Dr. Norman Dalton, "Enchondroma of Lung" (card); Mr. Lane, "Diphtheria of Larynx" (card).

16. *Wednesday.*

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

17. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

18. *Friday.*

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY OF LONDON.—Meeting. The following Papers will be read:—Dr. De Haviland Hall, "Sequel to a Case of Perichondritis of the Larynx;" Dr. Percy Kidd, "A Case of Tubercular Tumours of the Larynx;" Mr. Harrison Cripps, "Cases of Excision of the Rectum for Cancer;" Dr. Angel Money, "A Remarkable Case of Tubercular Meningitis."

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA, ESPECIALLY THOSE PREVALENT IN BENGAL.

By NORMAN CHEVERS, C.I.E., M.D.,

President of the Epidemiological Society of London.

(*Concluded from page* 450.)

Febris Exanthematosa Orientalis, otherwise Beriberi Fever.[39]

MUCH was said about the contagiousness of this disease, but no evidence of contagion is given, beyond the frequent occurrence of several cases in one family—which, standing quite alone, is, of course, no valid proof of the agency of contagion—and one very suspicious case mentioned by Dr. Harvey. Dr. Chambers, who was one of my most esteemed pupils and house physicians, considered that this "new disease" was relapsing fever. He does not appear to have found support from any other observer. He shows that a tendency to relapse marked several of his cases; but I cannot think that his patients suffered from true relapsing fever. I think that he saw an exanthematous fever; but he appears to place his fever cases apart from those which, he considered, resembled beriberi.

This epidemic was observed at Dacca and Sylhet, and at Shillong in the Kasia hills.

There does not seem to have been any appearance of the disease in Calcutta after the hot weather of 1880.

Between November, 1878, and June of the following year a similar epidemic prevailed in Mauritius. It was stated to have caused 729 deaths. Dr. Lovell, the chief medical officer, sent a report on this disease, which he termed "acute anæmic dropsy," to the Calcutta Medical Society, in July, 1880. I have already spoken of the exanthem which generally characterised this malady. In the worst cases, there were hydropericardium, hydrothorax, and ascites. Signs of scorbutus are not mentioned. "Europeans were entirely exempt." "The patients, generally Indians, were very anæmic, the blood watery, with marked diminution of the red blood cells, and increase of leucocytes and granules." "The urine was seldom albuminous." Enlargement of the spleen was not found to be a feature of the disease. Opinions of medical men were divided regarding the contagiousness of this malady; the majority were opposed to the view of contagion.

[39] Read before the Medical Society of London, March 31st, 1884.

A report which appeared in the first volume of the *Madras Quarterly Medical Journal*, page 70, shows, that late in the year 1829, beriberi, which had previously been unknown in that locality, attacked the Madras sepoys at Singapore, while "*the convicts remained without a single patient with the complaint.*" True beriberi prevailed in the criminal prison at Singapore in 1875–76–78–79, and 80. *It did not spread among the community at large.* No European or native female prisoner suffered. In 1878, the death-rate was 16·20 per cent. of admissions, and rose to 20·63 in 1879. There is no mention of fever or eruption. Rheumatic pains and paraplegia were frequent symptoms. The great serous cavities, peritonæum, pleuræ, pericardium, were filled with serum. Scorbutic symptoms appeared in some cases. *The urine was scanty, high-coloured and albuminous.* In a leading article in the *Indian Medical Gazette*, for September, 1880, Dr. McLeod observed that "as regards symptoms and mortality, the Calcutta disease presented a sort of transition between the pure beriberi of Singapore, with rheumatic and paralytic phenomena and albuminous urine, and the acute dropsy of Mauritius, which presented many of the features of a contagious exanthem."

I must repeat that my own inference from the evidence is, that the "new disease," as it occurred in Bengal and Mauritius, was an exanthematous fever. Its mode of invasion, when epidemic, would alone declare beriberi to be a fever. No one who has studied the natural history of fever will believe that the epidemic disease which, as we have seen, invaded Lower Bengal in 1877, and Mauritius in the following year, was either paraplegia or scorbutus, or consider that it was renal anasarca.

First.—Beriberi regarded as Renal Anasarca.

In a valuable but very rare volume,[40] "The Proceedings of the Hyderabad Medical and Physical Society," Mr. J. L. Ranking published, in 1853, a series of reports, tending to show that the previously obscure disease, beriberi, depended mainly upon the existence of a form of *morbus Brightii*. Mr. Ranking said that his limited experience led him to adopt the opinion that beriberi is primarily and essentially a renal disease; that deterioration of the blood is caused by lesion of the kidney, and that the "numbness" staggering gait, or more confirmed paralysis of motion (pointing to affection of the spinal cord), the "irritable" condition of the heart, the endo- or pericardial "inflammation" [?] and effusion (which latter is generally the immediate cause of death) are secondary affections. He showed that, in sixteen cases of beriberi, the urine was more or less albuminous in eleven; in eight, the microscopic elements characteristic of kidney disease existed. Microscopical examination was made in these eight cases only; so that, in every case of well-marked beriberi which fell under Mr. Ranking's notice, the microscopic evidences of kidney disease were discovered when sought for. In nine, there was general anasarca; in one, the anasarca existed with ascites; in two, there was delirium; in one, coma; in fourteen, numbness without actual anæsthesia; in two, impaired sensibility with numbness; in six, there was more or less loss of motor power; in seven, symptoms of pericardial and endocardial affection; in five, signs of œdema of the lungs; in two, hepatitis; in two, nausea and vomiting; in two, diarrhœa. It was noticed by Malcolmson that there were certain points of resemblance between beriberi and *morbus Brightii*. This resemblance forced itself upon Mr. Ranking's attention before he had access to Mr. Malcolmson's work. Upon commencing the examination of the urine of all beriberi patients, it was found that, although the quantity excreted, the reaction, specific gravity, colour, &c., differed according to the stage and form of the affection, the microscope revealed the presence of blood-discs and epithelial scales. In two cases there were also tube casts, and mucous and organic globules. The urine was often coagulable by heat and nitric acid, though never to a high degree albuminous. He represented that, in the earlier stages of beriberi the state of the urine points only to simple congestion or sub-acute inflammation of the kidneys. He found it to have a deep red colour, owing partly to the admixture of blood, partly to concentration; a specific gravity at or somewhat above the natural standard. A deposit of lithic acid and lithate of ammonia sometimes occurred, and abundant and large crystals of lithic acid. These morbid conditions of the urine will, Mr. Ranking considered, be found to precede the anasarca, numbness, and other symptoms of spinal affection. Unless the state of renal congestion, or sub-acute inflammation, upon which it depends, can be overcome, the anasarca continues, effusion "into the spinal cord" [?] takes place, the heart becomes involved, and effusion into the pericardium and pulmonary œdema carry off the patient. The urine remains scanty, in such cases, to the end, or is even totally suppressed. In more chronic cases, or in individuals who have struggled through the acute stage, the urine was found to alter in character—it increased in quantity, but decreased in density—it seldom, however, reached the healthy standard even as to quantity—it acquired a pale opalescent colour—had an alkaline reaction, a specific gravity of 1,010, and coagulated more or less by nitric acid and heat. "Here," said the author, "we have all the characters of the urine of 'Bright's kidney.'" "The alkaline reaction is due doubtless to the existing lesion of the spinal cord which, although in itself a secondary affection, reacts upon the urinary organs, the mucous membrane of the bladder especially, causing an increased secretion of mucus, or even pus, and consequent alkalinity of the urine. The microscope still reveals blood-discs; a great abundance of epithelial scales with mucus or blood globules entangling crystals of triple phosphate, or, if any deposit occurs, it is made up of mono-basic or bi-basic phosphates, amorphous phosphate of lime and mucus."

Others who observed beriberi nearly at the same time, noticed the renal complication.

In the middle of August, 1852 (dates are self-evidently of great importance in the correlation of cases of beriberi, as showing agreement or difference in type in the same or in other epidemics of the disease), Dr. George Mackay[41] admitted to hospital, at Rangoon, a Madras sepoy, who died, in about 26 days after sickening, with typical symptoms of beriberi. "The urine presented a copious deposit of mucus, with altered blood-discs and crystals of the triple phosphate." Many other cases of a nature similar to this came under Dr. Mackay's notice during the same (second Burmese) war, but none in which the symptoms so nearly resembled those of beriberi. His attention in those cases was early directed to the state of the urinary organs. "Epithelial scales, altered blood-discs, crystals of the triple phosphate being almost invariably met with; in some cases oxalate of lime crystals, and in one or two tubular casts were observed."

The "Hyderabad Proceedings," in which Mr. Ranking's paper appeared, also published a case by Mr. Maillardet. Dr. Van Someren also discovered "casts of uriniferous tubes, epithelial scales, altered blood-discs and octohedral crystals of the oxalate of lime."

[40] I only know of one copy, possessed by my friend Dr. Waring, C.I.E. I gave extracts from its contents in the "Bibliographical Record," attached to No. 2 of the *Indian Annals of Medical Science*, in 1854.

[41] *Indian Annals of Medical Science*, No. 5, p. 349.

We have here descriptions, by three observers, of the conditions of the urine in (epidemic?) beriberi as the disease presented itself within a short space of time—apparently a period of a few months—on the continents of Madras and Burmah. Although the above facts, being published in the *Indian Annals of Medical Science*, must have come before many observers in India, I do not find that Ranking, Van Someren, Mackay, or any one else recorded other cases of albuminuria, cast desquamation, &c., in beriberi. Was this because, during that particular epidemic and that one only, the kidneys suffered nearly as they do in the cognate but very distinct (from epidemic acute beriberi) exanthematous fever scarlatina? At any rate, regarding beriberi as a fever of this genus, I am quite prepared to find that, when the exanthem is checked by the "chill," so frequently mentioned as a prominent exciting cause in this disease, albuminuria may occur. It is clear, however, that albuminuria was not a marked feature in the late Bengal and Mauritius epidemic, although it is to be regretted that none of the reports which I have seen take any notice of the microscopic condition of the urine.

It will have been noticed that in the Singapore outbreak, which commenced in 1875, "the urine was scanty, high-coloured, and albuminous."

Undoubtedly the incidence of beriberi is especially directed to those who are the subjects of renal disease. It has always been observed that a very considerable proportion of the victims of this disease are drunkards. Intemperate European soldiers are liable to this malady; their officers are far less so, although they have not always escaped. Christie says, in his report on beriberi: "I have remarked that a very great proportion of the patients seized with this disease were men accustomed to lead a sedentary and debauched life, such as tailors, shoemakers, &c., who, when working at their trade, are often excused the duty of the field, and by their double earnings are enabled to procure a larger quantity of spirits than the other men." He adds, "I have never met with an instance of this complaint in a woman, an officer, or a boy under twenty." I was told at Aden, about ten years ago, that European soldiers posted there, who are temperate, generally escape; but that, when a man becomes a sergeant, he is not unlikely to take to free-living, and then probably is attacked with beriberi. At the same time it is clear that, while beriberi sometimes resembles Bright's disease, it by no means always assumes that character. Certainly it is not produced by the ordinary causes of renal anasarca; and, if some of the cases of beriberi, such as those observed by Ranking, Mackay and others, may be designated as examples of this form of general anasarca, ordinary renal anasarca is in no sense beriberi. The paraplegic element of beriberi is not characteristic of common *morbus Brightii*.

Second.—Beriberi viewed in its Paraplegic aspect.

One of the leading sequelæ of beriberi being anasarcous and dropsical effusion into the areolar tissue and serous cavities, the occurrence of spinal paralysis, in various degrees, as one of its complications, is clearly accounted for. As I have shown, in describing the Bengal epidemic, the stiffness of the lower limbs is frequently due to the presence of hard œdema, not to spinal paralysis; but, in many cases of beriberi, distinct impairment of motor and sensory power in the lower limbs has been observed.

In an abstract of Malcolmson's prize essay on beriberi, Sir G. Ballingall says: — "In dissecting patients who have died of this disease, serous effusions, more or less extensive, into the cellular substance, as well as into the great cavities, would seem to be the more prominent appearances; and, in addition to this serous effusion, there often exist in the lower region of the spine, about the origin of the lumbar and sacral nerves, symptoms of congestion; and, in one very remarkable case, of which the details are given by Mr. Malcolmson with an illustrative engraving, an effusion of reddish coagulable lymph had taken place on the posterior surface of the theca, at the fourth dorsal vertebra, and the same in the region of the sacrum."

Although the form of chronic paraplegia, termed by Bontius and other old writers on the diseases of the East "barbiers," is, as shown by Henry Marshall, quite distinct from beriberi, it can hardly be doubted that much of that which was formerly regarded as barbiers was, in reality, beriberi with spinal paralysis.

Lathyrism, paralysis of the lower limbs caused by habitual feeding upon the *dâl* of the *Lathyrus Sativus*, prevails extensively in Upper and Central India, especially near Allahabad and in Upper Scinde. M. Proust has observed it in the Jurjura mountains of Algeria, and it is stated to be far from uncommon in France. A recent writer having stated that lathyrism and beriberi are identical diseases, M. Pierre Marie[42] has undertaken to prove that such is not the case. It appears to me not improbable that the writers have confused beriberi with barbiers. At p. 113 of the *Indian Annals of Medical Science*, No. 23, Dr. James Irving has contrasted the symptoms and other conditions of lathyrism and barbiers. I should have considered beriberi and lathyrism as little congeneric as Monmouth and Macedon—beriberi being a very acute disease, lathyrism, as it occurs in India, a chronic one. But, since the question has arisen, M. Marie's paper calls for notice from medical men working in those districts, far separated as they are, in which lathyrism and beriberi are most common; lathyrism prevailing far inland, beriberi occurring almost entirely within the influence of the sea breeze. It appears singular that, in giving long and minute descriptions of the conditions of the lower extremities in the contrasted diseases, M. Marie appears to have overlooked œdema in beriberi.

The loss of power in the lower limbs, so frequently noticed in beriberi, appears to need clear definition. In what cases is it dependent upon spinal lesion, and in what others is it due to hard œdema of the extremities and debility? With regard to the former cases, one point ought to be cleared. Sir Joseph Fayrer has suggested the probability that filarious disease may be in some way concerned in inducing beriberi.[43] A form of spinal paralysis in the horse, *kumree*, which prevails within the Madras area of beriberi, and in Eastern Bengal, has been ascribed by Twining and others[44] to the presence of entozoa in the cord. Do spinal lesions in beriberi ever arise from this cause?

Undoubtedly, although spinal paralysis is a recognised sequel of beriberi, it cannot be considered that beriberi is, in any sense, paraplegia.

Third.—Beriberi regarded as an expression of Scorbutic Cachexia.

Marked evidences of scorbutus are so often noticeable as prominent symptoms in cases of beriberi, that at least one of our best Indian observers has considered that beriberi is essentially a form of scurvy.

Wishing to give fair play to this, as well as to all the other leading theories upon the causation of beriberi, I may cite the following rather striking example of this coincidence, as observed by Tumeez Khan, in Calcutta, in 1878, and others which I find in

[42] *Progrès Médical*, No. 43. An abstract of this paper is given at p. 606, *Medical Times and Gazette*, vol. ii., for 1883.

the *India Journal of Medical Science*, vol. v., N. S., p. 75, as occurring *circa* 1839 on a passage from Java.

1839.	1878.
A Dutch barque arrived in the Madras Roads, from Java, on the 12th May, having left Malacca, where she lay only three or four days, all being well, on the 7th April. The crew were Javanese, who had made objections about coming to the Coromandel coast, as they said "many of their countrymen had died of a similar disease on former voyages."	A Mahomedan ship-captain of one of the Arab sailing vessels which ply between Calcutta and Jeddah, a native of some part of the Coromandel coast, his son, and a third member of his family —both said that they had returned hale and hearty from a trip to Jeddah, the third person had died previous to Tumeez Khan's visit.
"About twenty days before reaching Madras, many of the crew were seized with swellings and numbness of the legs and feet, but yet were able to perform their duty; when they arrived within 50 or 60 miles of the coast, and within the influence of the land winds, in three cases the symptoms became much aggravated, they were unable to walk, dyspnœa and pain in the præcordia supervened, and they died the day after the ship arrived.	A short time after their arrival in Calcutta "both were nearly simultaneously attacked with febrile symptoms, which lasted for a few days, and were followed by œdema of the lower limbs, to which succeeded cough, and dyspnœa" (the son had hæmoptysis). The "œdema extended up to the loins." When visited, they had "orthopnœa, palpitation and inability to lie down." It is not said whether the father and son died, but they probably did.
"They were a wretched looking set, and were very badly fed, their rations consisting only of rice, and of that a very limited quantity. The water was bad, and they were on very short allowance."	"Both had spongy and discoloured gums."

In connection with the above observations, all who are desirous to investigate the nature of beriberi ought to study Morehead's chapter on this disease. His data are mainly derived from histories of "beriberi as it occurred among the Lascar crew of the ship *Faize Allum*, in May, 1853, when in lat. 10° north, within sixteen days' sail of Bombay, and from an account of an outbreak of "epidemic ascites," or "peritonæal dropsy," in thirty of the crew of H.M.S. *Juno*, on her arrival at Sydney from a lengthened cruise among the islands of the Pacific, in January, 1856."

The native subjects, four cases of beriberi, from the ship *Faize Allum*, whom Morehead treated, were doubtless scorbutic; the men of the *Juno* were probably so. Morehead does not appear to have met with any other cases of beriberi. He considered that "beriberi, more particularly in its acute form, occurs usually in persons favourably circumstanced for the development of a scorbutic taint, and subsequently exposed to cold, dry or moist winds, or to lying on the ground wet with rain or dew." With the judicious circumspection, which characterises all his reasoning, he observes that to him "it seems that beriberi is a general dropsy, and that, in regard to each instance, the question ought to be—what is the pathology of this case of general dropsy?" He adds, "generally it will be found that a scorbutic diathesis and external cold or wet, are the determining conditions."[45] Dr. Peet adopts this view without qualification. He says, "When individuals who are scorbutic are exposed to cold and alternations of temperature, they are not unfrequently attacked with general dropsy. It has been customary to designate the disease now referred to as beriberi."[46] Here is, I think, another example of the common error of regarding as cause and effect two circumstances which are merely associated as frequent coincidences. It is to be borne in mind that beriberi is often epidemic, which scorbutus cannot possibly become. There was no beriberi among the scorbutic mariners of last century; and in many cases of sea scurvy, which I have treated, there was not the very slightest evidence of its existence. Beriberi occurs in some localities notorious for scurvy, as Aden; but it does not prevail in certain of those districts of Hindustan—as the province of Behar, and in Scinde—in which scurvy is extremely prevalent. Scorbutus, as we have already seen, occurs in Lower Bengal, but not so extensively as in some other Indian districts. The recent Bengal epidemic frequently attacked the scorbutic, but it was noticed that many of the sufferers from the epidemic were free from evidences of scorbutus. I think that, when we state the fact that wherever beriberi prevails, it especially selects the scurvied, we are free from the error of supposing that acute beriberi is an expression of scorbutic cachexia, although scorbutus should be looked for in all cases of beriberi, and be treated, when present, as a grave complication.

[45] *Op. cit.*, pp. 707-8.
[46] "Principles and Practice of Medicine," p. 570.

Fourth.—Is Beriberi, as some have considered, a form of Malarious Cachexia?

I think that this question must be answered in the negative. Beriberi prevails in localities, such as Aden and Mauritius, where the paludal poison does not abound in great intensity. Until 1877, the Delta of the Ganges, that hot-bed of marsh influence, was never visited by this pest as an epidemic, and has never generated endemic beriberi. I believe that, up to the time of my leaving Bengal, eight years ago, it was never suggested that beriberi could originate there. Considering that a vast number of sailors pass through the Calcutta hospitals, I think it noteworthy that only one not unquestionable case of this disease, in a half-caste seafaring-man, made its appearance in my wards. No one acquainted with the natural history of the marsh poison would, in studying the outbreaks of beriberi in Calcutta and Mauritius in 1877 and the following year, consider that there could have been any interchange of paludal influence between these two widely separated localities. Nevertheless, seeing how generally and how often gravely prevalent malarious cachexia is in most of the regions which beriberi visits, the necessity of searching for it, as a most serious complication, must never be overlooked. Few constitutional states can be regarded as more perilous than that of the multitudes of unfortunates who, being the subjects of the combined cachexiæ of marsh-poison and scorbutus, are attacked with beriberi.

I think that we are justified in concluding that beriberi is not a malarial fever, but that the victims of malarious cachexia are especially liable to suffer from its attacks.

Treatment.—If I am right in the firm belief which I hold that true beriberi is an exanthematous fever which, although wholly *sui generis*, pursues a course which, in more than one of its leading actions, much resembles that of scarlatina, it is evident that here our first object should be, as it is in scarlatina, to endeavour to see each case *ab initio*, and to prevent the occurrence of renal and other visceral mischief, anasarca and dropsical effusions into the serous cavities. If it could be my duty to have charge of military and jail hospitals within the endemic area of beriberi, every European soldier, sepoy, and prisoner, would be warned to seek relief from my assistants *immediately upon being attacked with even the very slightest symptom of fever.* I would myself examine all fever cases early, within twelve hours if possible, carefully searching for the exanthem on the lighter skins, and considering that, if I frequently discovered it there, its presence might be suspected in those of darker complexion. Then the chief indications would be:—To admit all fever cases as in-patients; to avoid the occurrence of that CHILL so frequently assigned as the cause of general anasarca in beriberi; to promote healthy cutaneous action and to subdue fever; to discover and deal with pre-existing renal and other visceral disease, and with malarial and scorbutic cachexia. After remaining for two or three days under observation, the cases of ordinary intermittent fever would explain themselves, and would then demand

less close attention. When patients do not seek relief until general anasarca has become established and, being too weak to go about, are desirous to come to the hospital as a refuge, the same principles of treatment ought to guide us. With the deepest respect for the memory of a great Indian physician, I cannot agree in the validity of his maxim, guarded as it is, "remove the dropsy by purgatives or diuretics, being guided to the use of the one or the other by the state of the pulse." I would no more give direct diuretics in the anasarca of beriberi than I would in that of scarlatina. My great effort would be to obviate renal congestion in all possible ways, and to make the work of the kidneys as easy as possible. I would not give anything more drastic than the mildest laxatives in these cases, liable as they are to end fatally by diarrhœa or dysentery. If we can only remove the other complications of beriberi, the anasarca will undoubtedly disappear as constitutional power becomes re-established. No purgative or diuretic will, except by promoting exhaustion, touch a pericardial, arachnoid or pleural effusion which threatens life.

I believe that, fifty years hence, the futile and destructive practice of endeavouring to remove dropsical effusions by the use of drastics and direct diuretics will be viewed as one of the most barbarous therapeutic errors of the present century.

I think that the whole subject of acute and chronic beriberi, especially as they occur in the Madras Presidency and in Ceylon, ought to be thoroughly reinvestigated by sound pathologists. Work out the subject of beriberi, is one of the best pieces of advice that can be given to a young physician entering upon a career in the Madras Presidency.

The field of observation is large. In 1881, there were 102 cases of beriberi, with twenty deaths, among the native troops in the Madras Presidency, in a strength of 30,394. No cases occurred in the Bengal and Bombay Presidencies.

Especial care should be taken to ascertain the precise nature of what is termed the "chronic" form of beriberi. Are these cases of malarious and scorbutic cachexia, not allied to true beriberi, or are they examples of repeated attacks of beriberi and consequent ill-health? Christie observed that, "men who have once had the complaint are the most subject to it in future." In the epidemic and acute form, light is needed with regard to the precise type of the fever, the character of the exanthem, the range of temperature, the chemical and microscopical conditions of the urine, &c. All observers have noticed that, although the œdema of the lower limbs is hard, the serous effusions, arachnoid, pericardial, pleural, and peritonæal, the pressure of which tends to cause death in beriberi, are distinctly *non-inflammatory*. A little sifting would clear this question, enabling us to judge whether we ought or ought not to draw off the fluid from the pleuræ and pericardium, and with what prospect of success.

ABSTRACT OF CLINICAL LECTURE ON IMPASSABLE STRICTURE OF THE URETHRA.[1]

By EDMUND OWEN, F.R.C.S.,
Surgeon to the Hospital.

GENTLEMEN,—By the term "impassable," as applied to a urethral stricture, one expresses the fact that though urine may manage to escape by the meatus, the surgeon is unable, after careful and prolonged attempts, to pass an instrument through it into the bladder. Most strictures of the worst inveteracy permit of a leakage from the distended bladder an overflow; indeed, whenever the surgeon hear, that an adult is the subject of urinary dribbling — incontinence the patient will call it — he may expect to find the viscus full and running over. (In childhood, however, matters are different.) It is theorised that if the urine can pass outwards the surgeon ought to be able to introduce a slender flexible catheter into the bladder, or at least a filiform bougie, which latter instrument, by lying in the narrowed passage, would determine its continuous dilatation. Sometimes such a mastery can be obtained over an obstinate stricture. There still remains the fact, however, that some strictures are impassable; such form the subject of the present lecture.

The usual history of these cases of impassable organic stricture is this:—Many years ago—five, ten, twenty—the patient was the subject of a gonorrhœa, which, he fancies, was never completely cured, and which eventually tailed off into a gleet, but at times seemed quite to cease. Or it may be that the first attack got apparently well, but that at almost every subsequent exposure to infection a fresh attack was contracted, the fact being that the original gonorrhœa was never completely cured. The occasional passage of a full-sized bougie then would have made him sound and well, but now after years of annoyance the ever-diminishing stream of urine has ceased, and the patient is in the agony of an over-distended bladder, which the surgeon is unable to relieve by a catheter. The full bladder is forming a rounded tumour, which is dull upon percussion, and which bulges forward between pubes and umbilicus, and backwards towards the rectum, where it can be felt by the finger *per anum*. To give such a one full doses of opium to allay his distressing symptoms is but to hide them for a time without removing their cause, and so the risk of the occurrence of rupture of the urethra behind the stricture, with extravasation of urine, will be increased.

It may be that considerable time has already been expended in futile attempts at relieving the distension by hot baths. The patient is in agony, and bathed in perspiration, and immediate relief is demanded.

Years ago, such a case would most likely have been relieved by a puncture of the bladder through the rectum, by such a canula and trocar as I hold in my hand. The base of the bladder would have been perforated above the prostate where it is devoid of serous covering. Possibly, after the canula had been retained in the bladder for a day or two, and matters had quieted down, the surgeon might have succeeded in passing a small catheter *per urethram*, and treated the stricture by gradual or continuous dilatation. The employment of this instrument was not without its objections and dangers, and it has now given place to the aspirator; with it the urine can be drawn off at once and without much risk. The rounded tumour must be boldly attacked by the fine, hollow needle through the linea alba, but care must be taken that the needle passes really into the bladder, and is not allowed to run down between the front of the bladder and the abdominal wall. I have seen this happen. Of course, the needle is withdrawn after the operation, to be re-introduced on subsequent occasions as often as may be necessary. And so a catheter may, after due rest, be made to find its way into the bladder. But if, after all this, the stricture (which is felt hard and cartilaginous by the perinæum) remain obdurate, or if the presence of perinæal fistulæ demands a cutting operation, the patient must be forthwith prepared for the ordeal, which will be for his constitution a trying one, on account of the long persistence of the stricture being almost necessarily associated with organic or functional renal disease.

The bowels having, if practicable, been cleared by a full dose of castor-oil, or by the administration of an

*

[1] Delivered at St. Mary's Hospital, March 19th, 1884.

enema, the patient is to be anæsthetised, and a final attempt made to pass a fine-grooved staff into the bladder, which shall be a guide in the division of the stricture. This failing, the patient is to be placed in the lithotomy position, the knees being held symmetrically by two able assistants, one of them also holding the scrotum up out of the way. Then the left index finger of the surgeon, as he sits at the patient's breech, is to feel and rest against the apex of the prostate, and the point of a large scalpel is to be thrust through the perinæum, at about an inch in front of the anus, so that the point transfixes the triangular ligament and opens the dilated urethra just in front of the apex of the prostate. Then the blade of the knife is carried boldly forward through the hard and thickened tissues about the perinæal urethra, and into the base of the scrotum. This part of the cutting being thoroughly done in the one sweep; a large steel bougie with a bulbous end is to be passed through the penile urethra, and, along the depths of the wound into the bladder, and after its withdrawal, a full-sized metal catheter, No. 13, 14 or 15 (English gage), is to be introduced and the bladder evacuated, and, if necessary, washed with some acidulated solution. Bleeding having ceased—and, as a rule, it is not serious—the patient is to be returned to bed, wrapped in a blanket, with hot bottles beside him. He is to be stimulated with ammonia and brandy, if necessary. If opium be prescribed, due heed must be given to the crippled condition of the kidneys. No catheter is to be retained, even for an hour, in his bladder; if the perinæal section has been properly performed there will be no difficulty in introducing a No. 13 or 14 on the third day, and that without the need of ether or chloroform. Severe rigors are apt to follow, but, as a rule, the patients steadily improve from shortly after the operation, the perinæal wound granulates up; the catheter is passed every second or third day, and eventually the patient, having learned to pass it for himself, becomes master of the situation.

In this account there may be nothing new; but there are one or two points in connection with the operation and treatment to which I would like specially to refer as worthy of attention. In operating, no heed should be given to the median raphé, as it is not a trustworthy landmark; inflammatory adhesions or abscesses may have shifted it considerably to one side of the median line. The patient being held straight and squared upon the table the landmarks are the apex of the prostate as found by the finger in the rectum, and the middle line of the body, as traced by the eye from the anus over the pubes and up towards the umbilicus. The incision made forwards from in front of the anus and into the base of the scrotum should be bold and free. The catheter No. 14 or 15 should then be passed. When I was a student a surgeon would have shuddered at the thought of attempting to pass such a catheter, but since Otis has shown how large an instrument the normal urethra will receive without damage, it is evidently expedient that the renewed portion of the canal should be restored upon the largest scale. Fifteen or twenty years ago the passing of No. 9 would have satisfied the operator, and this instrument would have been tied in the bladder for 24 or 48 hours. At the present day no instrument is tied in, the surgeon relying on his being able to pass a No. 14 or 13 on the third day. If I pass No. 15 at the operation, I am content with No. 14 on the third day; if No. 14 at the operation, then No. 13 on third day. Then, as the wound begins to close, the patient is taught to pass 13 or 12 for himself. When he can do this easily and fearlessly he is allowed to go home, being made thoroughly to understand that his future happiness depends upon the systematic introduction of the instrument at least once a week. My advice to such a one is that he become a water-drinker; alcohol and its associations are ruin to a man with urethral stricture, even when he thinks that he has the stricture well under control.

The last point for remark is this, which I will put in the form of a question. When through the site of an impassable stricture, a urethra has been restored of sufficient size to admit the passage of a No. 13 catheter, of what material have the walls of the new channel been composed? It matters not what the operation was, Wheelhouse's, or the ordinary perinæal section as described above; the question applies with equal force if the hard tissues have been divided on a grooved staff passed through a stricture. If No. 1 or 2 only could pass before the external urethrotomy, and 12 or 13 is passed, subsequently how was the new canal made? The answer is that the canal must be established out of the peri-urethral fibrous tissues, which readily yield themselves for the purpose. Eventually the new canal becomes lined and velvety, and as little inclined to complete obliteration, as the mucous off-shoot of an anal fistula.

Case I.—G. B., aged 51, traveller, August, 1881. Gonorrhœa, twenty years ago; some months since a surgeon tried to pass a small catheter, so much bleeding followed, that his room "looked like a slaughter-house," then 40 hours complete retention; has lately passed "matter." Several colleagues tried to introduce a catheter. Perinæal section, No. 13; 40 ounces of purulent urine withdrawn, death next day from suppression of urine.

Autopsy.—Kidney pale, capsule strips off easily, cortex slightly injected, no emboli anywhere.

Case II.—W. L., November, 1881. Old stricture, several attacks of retention, urinary extravasation, perinæal section, No. 13; made complete recovery, learnt to pass No. 12.

Case III.—W. G., aged 38, painter, November, 1882. Traumatic stricture in 1868, for last six years all urine has been passed by fistula half-inch in front of anus. Admitted with complete retention, by aspiration 40 ounces urine removed, then urine appeared again through fistula, on eighth day perinæal section, rigors, sixth week discharged, passing No. 12.

Case IV.—W. T., aged 63, shoemaker, January, 1883 Gonorrhœa and gleet for past three and a half years, one year ago perinæal abscess, rigors after futile attempts at catheterisation, perinæal section, No. 13 passed. Temperature 105·8, rigor, cystitis, bladder irrigated. Last note February 11th, "No. 13 passed," patient declined further treatment.

Case V.—H. M., aged 41, stoker, September 14th, 1882. Gonorrhœa twenty years ago, four or five years ago soft catheter was passed, stricture increasing, ten days rest in bed, urine alkaline, patient uncomfortable, no catheter passed, perinæal section, No. 13; bladder irrigated; eighth week patient went home, having learned to pass No. 12.

Case VI.—J. C., aged 43, labourer, March, 1883. Second attack of gonorrhœa in 1871, lasting two months, many unsuccessful attempts to pass catheter during month's rest in hospital; rigors, perinæal section, eventually discharged, passing No. 14 easily.

Case VII.—W. S., smith, January, 1883. Gonorrhœa twelve years ago, followed by gleet and stricture; had been out-patient; two weeks in hospital, temperature rose to 104°, very ill, shiverings, diarrhœa, perinæal abscess; perinæal section, No. 13 passed; much better, then chronic pyæmia, discharged convalescent, and passing No. 13.

Case VIII.—W. C., aged 33, sailor, March, 1883. Ten years ago gonorrhœa, which lasted indefinite time. Eight years ago admitted to St. Bartholomew's Hospital for retention, but no catheter could be passed, water came away in hot bath. Within eight months perinæal abscess, now closed, retention, aspiration, perinæal

section, No. 15; rigor; discharged convalescent, passing No. 14.

Case IX.—W. N., aged 54, May, 1883. Stricture coming on since gonorrhœa 28 years ago, worse within last three years; after three weeks in hospital, stricture unyielding; perinæal section, No. 15, discharged convalescent, passing No. 12.

Case X.—T. S., aged 58, labourer, February, 1884. Gonorrhœa 24 years ago, and six months after beginning of attack, was told by a surgeon that he had a stricture. Perinæal fistulæ, tissues as hard as cartilage, bladder bulging to umbilicus, and "not been emptied for years," urine albuminous and purulent. Perinæal section, No. 14; 40 ounces smoky urine withdrawn, up and convalescent, No. 13 passes easily; still under treatment. (This man was lately in a provincial hospital, no instrument could be passed, and he was sent home with bladder engorgement unrelieved.)

Case XI.—T. H., aged 51. "May have had gonorrhœa years ago when in Royal Artillery;" stricture six or seven years, perinæal fistulæ, tissues very hard. Perinæal section, February 29th, 1884; now convalescent, but under treatment, house surgeon passes No. 14 easily; patient is to be taught the art, and to go home.

UNIQUE CASE OF CONSERVATIVE SURGERY.

By WM. JAS. SPENCE, L.R.C.P., &c.,
House Surgeon, Bradford Infirmary.

Sacrificing parts for the sake of making neat-looking flaps, or in order that recognised operations may be performed, is, in my opinion, most unjustifiable. Only parts injured beyond repair should be removed, unless the result by so doing is likely to impair the usefulness of the remainder. An unseemly stump, if useful in the slightest degree, is better than none at all. When the parts are left to granulate and heal—providing there is a covering of viable tissue—the result is seldom or never disappointing, Dame Nature does her work well.

In no part of the body is conservative surgery of so much importance as in the hand. Its extreme usefulness renders the utmost caution necessary in removing parts of it.

The principle contained in the above remarks led me to attempt to save the thumb in the following case:—

Annie B., aged 18, a weaver, was admitted to the Bradford Infirmary under Mr. Meade, on January 18th, 1884, for injury to right hand, caused by the cog-wheels of some machinery she was attempting to stop. On admission I found the whole of the hand to the ulnar side of an oblique line, extending from the metacarpo-phalangeal joint of the index finger to the middle of the carpus, reduced to a pulp; the metacarpal bone of the index finger was also irreparably injured. In fact, only the thumb with the scaphoid, trapezium, and trapezoid bones of the carpus remained uninjured.

I was at first undecided what to do. I could amputate at the wrist-joint, by taking an external flap from the soft parts covering the metacarpal bone of the thumb—an operation described by Dr. Dubrueil, in his work on "Operative Surgery." This would make a neat flap and a seemly looking stump, but the uninjured thumb would be sacrificed. Secondly, I could leave the three uninjured carpal bones with the thumb attached to granulate and heal over, but this, with the other four carpal bones away, would leave a flail-like appendage of little or no use, and only in the way.

With reference to leaving the whole or part of the carpus, Dr. Bell, in his "Manual of Surgical Operations," has the following:—"In cases of injury, where the carpus is opened, and the hand irreparably destroyed, the question arises, Where ought the amputation to be performed? To this we answer, that there appears no conceivable advantage to be gained *by leaving all or any of the carpal bones.* If successful, it would result only in the retention of a flapping joint, useless from there being no tendons to act upon it, except the tendon of the flexor carpi ulnaris. . . . ." (The italics are my own.) I was reluctant to sacrifice the thumb, and adopted the following course to retain it. I removed the remaining uninjured bones of the carpus, and the whole of the injured metacarpal bones, leaving only the thumb and its metacarpal bone. I next brought the articular surface of the proximal end of the metacarpal bone into contact with the articular surface of the radius. The soft parts surrounding the thumb formed a good covering for the ends of the ulnar and radius when united by sutures with the uninjured soft parts of the forearm. The thumb was kept in position by an interrupted splint. I was very doubtful at first whether a useful attachment would result, but I reasoned that, if unsuccessful, the thumb could always be removed, later on. The parts healed kindly, and the patient, after some five weeks stay in the hospital, was discharged cured. At first there was very slight movement of the thumb, but this has gradually improved and will, in time, I have no doubt, be considerable. The patient tells me she finds it very useful, being of great assistance in fastening her clothes, &c.

ON THE ÆTIOLOGY AND PATHOLOGY OF CHOLERA.[1]

By GEORGE GULLIVER, M.B. Oxon., M.R.C.P.,
Assistant Physician to St. Thomas's Hospital.

Dr. Gulliver said that though the mode of origin and propagation of cholera had been raised during the debate on Sir W. Guyer Hunter's Report, it was in reality a side issue, that paper being concerned only in showing that the disease was not imported into Egypt; the story of its having been so imported having no foundation in fact, and the disease being endemic in the country at a period long antecedent to the outbreak. At the request of the President he had brought forward a few of the facts bearing on the ætiology of cholera generally, without special reference to Egypt.

He thought that few would deny that cholera is a specific disease; probably no great number would object to its being called a specific febrile disease. The ordinary symptoms and pathological appearances necessary to complete the definition were not dwelt upon, as being well known to all. The value of a knowledge of the anomalous and latent cases in investigating the ætiology of specific diseases was then dwelt upon, and it was held to be a great cause for regret that we knew so little of such cases in the case of cholera, the reason for this being obvious. The consequence was that our knowledge of the ætiology of cholera was in a very much more backward condition than in the case of other specific diseases.

Assuming that cholera is a specific disease, he had no hesitation in saying that it depended on a specific poison which entered the body from without. The

[1] Abstract of a paper read before the Epidemiological Society, March 12th, 1884.

principal views on the mode of propagation of the disease were then enumerated :—Firstly, that it is contagious; secondly, that it is never contagious, and that the poison is generated and propagated independently of man ; thirdly, Pettenkofer's belief that it is contained in the excreta, but requires the soil to act as an intermediary host before re-entering the body of man; and fourthly, certain views less definite than the foregoing. Dr. Gulliver then insisted on the great importance of the predisposing and exciting causes of the disease, so great that we might almost be in danger of mistaking them for the specific poison itself. Probably the *rôle* played by them was without parallel in the history of specific diseases in which the poison enters the body from without. A comparison was made with what takes place in gout, where the exciting causes play such an important part in rousing into activity the poison latent in the blood, the difference being that in the case of cholera, the poison was not in the blood but in the surroundings, only wanting a predisposing or exciting cause to enable it to enter the system. The question of a definite particular contagium was then dwelt upon, in entering upon the discussion of the first view, which holds that the poison is communicated from man to man. For the present it was thought that we were not in a position to say that this had been demonstrated, but it was pointed out that an apparent apathy exists in the search after similar organisms in enteric fever, the reason being that the contagious nature of that disease was firmly established apart from the demonstration of any organism. Unsanitary conditions had performed for us many experiments on human beings, and it remained to be asked, whether they had not done so in the case of cholera also. It was held that they had done so, and the well-known outbreaks in Broad Street and at Theydon Bois, and other facts in relation to its spread in Europe and to America, were advanced as evidence, it being pointed out that one positive fact is worth a great many negatives.

The second hypothesis, which denies the propagation of the disease from man to man, was then passed in review, and it was pointed out that those who hold it seem to regard the poison as of an atmospheric and telluric nature, some of them apparently claiming for it an affinity with the malarial poison. That no such relation exists was insisted on, inasmuch as the one is the type of an epidemic and the other of an endemic poison. The subject of an "epidemic constitution" was then discussed, and it was freely admitted that there are cosmic conditions which at times greatly modify the character of epidemics, but this is just as true of epidemics of diseases which are virulently contagious, such as small-pox, as of those which are doubtfully so. It was further shown that no hypothesis, except that of an epidemic constitution, would account for the spread of small-pox in 1870-73 throughout Europe. No doubt such conditions played a very important part in the spread of cholera, which being admitted, prevented the writer from believing that the theory of its spread by contagion was inadequate. He thought that the difficulties in explaining outbreaks in the East arose largely from the simplicity of the manner in which the natives lived, the complexity of the problem, which presented itself to the sanitary investigator, increasing in exact ratio with the primitiveness of the customs prevailing. For this reason our knowledge of the ætiology of enteric fever would probably be still on an unsatisfactory footing if it rested on observations made in Eastern countries only.

In conclusion, the author briefly referred to the Egyptian outbreak, pointing out that, though it afforded no conclusive evidence on the question to be discussed, yet such evidence as it did afford by no means weakened the opinion that cholera was a contagious disease.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

GLASGOW OPHTHALMIC INSTITUTION.

CASE OF ACUTE DELIRIUM CAUSED BY ONYX AND HYPOPION IN BOTH EYES, THE RESULT OF AN EXPLOSION—CURED BY AN OPERATION.

By J. R. WOLFE, M.D., F.R.C.S.E.,
Surgeon to the Glasgow Ophthalmic Institution, and Lecturer on Ophthalmology in Anderson's College.

In the *Practitioner* of January, 1884, the writer reported the case of Peter Campbell, quarryman, in which he transplanted conjunctiva from the rabbit for the cure of symblepharon of the left eye and formed a new eyelid on the right eye nine years ago, by transference of a skin-flap from the arm. The injury was caused by an explosion of gunpowder in blasting rocks. His brother Archibald, aged 35, was working in the same quarry and met with a similar accident on January 14th, 1884. When he was engaged in blasting a rock about thirty feet above the level of the ground, an explosion took place, injuring his face, eyelids, and both eyes. The following day he was sent by steamer to Glasgow, and arrived at the Ophthalmic Institution on the 17th. On admission, both eyes, face, and forehead were covered with powder and *débris* from the rock and the eyelids were swollen and tense. The conjunctival sacs and corneæ having been cleaned from the powder and *débris*, and atropinised castor oil applied, the patient was put to bed. The following day the swelling of the lids was found to be on the increase ; they were stiff and hard, had a charred look, could be raised with difficulty, and only by means of the elevators. Two days after admission the patient began to exhibit brain symptoms. He suffered from insomnia, with occasional delirium ; the pulse was quick, temperature 102°, the tongue was brown and parched, there was complete loss of appetite. On the following day the delirium increased ; there was constant spitting, picking of the bedclothes, and tearing his shirt. So restless and excited was he, that two men were constantly employed in keeping him down in bed. There was no ground for the idea of *delirium potatorum*, as the man had been an abstainer for ten years. The temperature had risen to 105°, the pulse could not be counted because of the patient's extreme restlessness. The swelling of the eyelids continued to increase, and was attended with a flow of tears and muco-pus. Every attempt to examine the interior of the eyes proved fruitless, and all the attention was concentrated, and the treatment directed, towards the general condition, which was considered rather precarious. He was treated first with morphia injections, then with bromide of potassium, and ice applied to the head, without the slightest effect, but, if anything, rather aggravation of the symptoms. A consultation was held with Dr. Cumming, who considered that there was considerable cerebral mischief, which was very likely caused by the accident ; and it was thought necessary to send the patient away to a general hospital. At the same time it was thought advisable, before sending him away, to examine the condition of the eyes, and to do what was necessary for them, that, in case he recovered, which appeared very doubtful, his eyes should not be completely lost. For this purpose he was put under chloroform and the lids lifted by elevators, when the right eye was found to be

suffering from a large corneal abscess and purulent infiltration, the sclerotic being marked by powder and *débris*. The aqueous chamber of the right eye was infiltrated with pus which obscured the pupil.

I punctured both corneæ and let out the pus, both eyes were very tense, and so hard that the lance could scarcely pierce them. The patient was ordered to be conveyed to the Western Infirmary as soon as he came out of the chloroform. To my great astonishment, by the time that he reached the Infirmary, his delirium had entirely disappeared as if by magic; and he spoke so sensibly to the medical officers of that institution, that, notwithstanding the medical certificate, they declined to consider it as a case of brain affection and refused him admission. Indeed, the patient at once began to improve in his general health. There can be no doubt, therefore, that the delirium was owing entirely to the process of suppuration going on in the eyes, and as soon as the pus was evacuated, the brain returned to its normal condition and function. He remained, however, perfectly oblivious of all that had taken place between the 17th and the 22nd, that period was a perfect blank to him. He made an uninterrupted recovery. The right eye suppurated; but the left recovered with a slight corneal opacity.

DENBIGHSHIRE INFIRMARY.

SURGICAL CASES.

By T. HAMMOND WILLIAMS, L.R.C.P., &c.,
Resident Medical Officer.

Extraction of a large Salivary Calculus without Incision of Duct.

An exceptional example of a large salivary calculus came under my notice, which is perhaps worthy of record.

H. J., aged 48, an intelligent man, gave the history of a swelling in the submaxillary region of three months' duration. As the gland enlarged, it became very painful, so much so that any movement of his tongue and even deglutition caused severe pain. The pain was most acute during mastication, but subsided when the process was over. On examination, I found the submaxillary gland enlarged, and painful on pressure. The opposite gland was also hypertrophied, though the patient did not complain of it, neither had he detected any fulness in its region. On applying one finger under the tongue, and another beneath the jaw, a hard lump was detected which, on pressure, gave a feeling of crepitus. There was no appearance of a cyst, and the submaxillary duct was empty. With manipulation the obstructing body, which proved to be a calculus, was found to be movable, and by a little daily pressure continued for a fortnight, it was gradually squeezed towards the mouth of the duct at the side of the frænum linguæ; ultimately after dilating the duct by means of a suitable forceps, the calculus was extracted in two pieces; its end having been broken off, probably when examining the gland, which accounts for the crepitus that was felt. The calculus was found to be oval in shape, one inch exactly in length, and three-quarters of an inch in circumference, and weighed eighteen grains.

In about a week the affected gland had diminished much in size, and the opposite one appeared to have regained its normal condition. The duct still remains thick, its opening gapes, and its canal is the size of a crow-quill. The patient now only complains of stiffness during mastication.

Remarks.—The gland opposite to the affected one, was evidently in a state of compensatory hypertrophy, which soon disappeared after the removal of the calculus. The patient stated that he had been treated for neuralgia, and various other complaints, and the case shows the importance of careful digital examination within the mouth, as well as under the jaw. No ranula was present, which is now known not to be due to any obstruction of a salivary duct, but to obstruction of mucous glands situated beneath the tongue.

Partial Dislocation of Bones of Forearm laterally.

A strong boy, aged 12, came lately under my care, who gave a history of having fallen from a wall on his side, with his arm twisted underneath him. On examining his elbow-joint, there appeared to the eye some deformity, and on measurement, the breadth and circumference of the joint were greatly increased, as compared with the opposite healthy joint.

The forearm was in a state of semi-flexion, and fully supinated. Motion in the joint was impeded, and excruciating pain was complained of in the course of the ulnar nerve.

The nature of the accident was ascertained by the circumstance of the great increase of the space betwixt the prominence of the olecranon, and internal condyle of the humerus. In addition, the cup-shaped head of the radius was found to be resting on the back and external border of the external condyle. A depression was detected just in front of the tip of the external condyle at the superior and outer part of the forearm. The external condyle was made out with difficulty, but the inner condyle presented itself as a marked prominence. When the patient was fully under the influence of chloroform, the sigmoid cavity of the ulna was found articulating with that part of the articular surface of humerus, appropriated to the head of the radius. The articular surface of the ulna apparently had passed over the prominent part of the trochlear surface of the humerus, caused, no doubt, by lateral force. Rotation of the wrist was limited and painful, and the forearm could not be further flexed.

Reduction, under chloroform, was easily done by manipulation, and the limb afterwards placed on an angular splint, with an elastic bandage. The great extent of the articular surfaces in their transverse direction, the reciprocal union of their inequalities, and especially the strength of the ligaments and muscles, give great strength to the articulation, and render it impossible to effect, by any violence, a complete dislocation laterally, unless compound. Partial luxations of both bones outwards are not common, and are much less frequent than the backward dislocation.

Chronic Mercurial Poisoning.—Two cases are reported from Nüremberg (*Berliner Klinische Wochenschrift*, No. 53, 1883) of chronic mercurial poisoning due to a simple and perhaps hitherto unrecognised cause. Amongst the artisans especially liable to the affection, mirror manufacturers have always held a foremost place, but the noxious properties of mirrors have been supposed to cease with the completion of the silvering process. In these cases, reported by Dr. Neukirch, all the well-recognised symptoms of quicksilver poisoning were present, and further, the presence of mercury in the urine was clearly established by chemical analysis. Every possible source for the poison was investigated without result, until an examination of the sleeping apartments disclosed the presence of some old mirrors in which the silvering amalgam had become soft and liquefied, and from which vaporisation of the mercury had evidently been slowly progressing. Removal of these mirrors was in both instances followed by complete recovery.

Medical Times and Gazette.

SATURDAY, APRIL 19, 1884.

But for the great function still in process at Edinburgh, the week has been singularly barren in events of medical interest. It is not every day, however, that a big University celebrates a centenary, and happening, as it does, in Easter week, the Edinburgh celebration is attracting the full attention that it deserves. The custom of holding anniversaries on the slightest pretext is not altogether an innovation—for an innovation it is, in this country at all events—which can be regarded with satisfaction. Such celebrations are often a sign of weakness rather than of strength, and are greedily seized upon, by comparatively modern and but moderately successful institutions, to advertise to the world that they have a history, if nothing else, to recommend them. Such ancient foundations as, say, the University of Oxford and Westminster Abbey, if they wished to celebrate a centenary, would have some difficulty in fixing upon what year in the century to hold it. But if ever a centenary was justifiable, it is so in the case of the University of Edinburgh, which, though but a youngster compared with our older foundations on this side of the border, has had such a remarkable career, has so influenced education throughout the world, has so attracted the love and respect of its *alumni*, and is altogether so flourishing and successful, as to stand in need of no advertisement. Her history was inversely typified in the quaint procession of students, who flung their torches together to form one monster bonfire. She has been the glowing fire at which an unending procession of students have kindled their torches, and borne them burning to the uttermost ends of the earth.

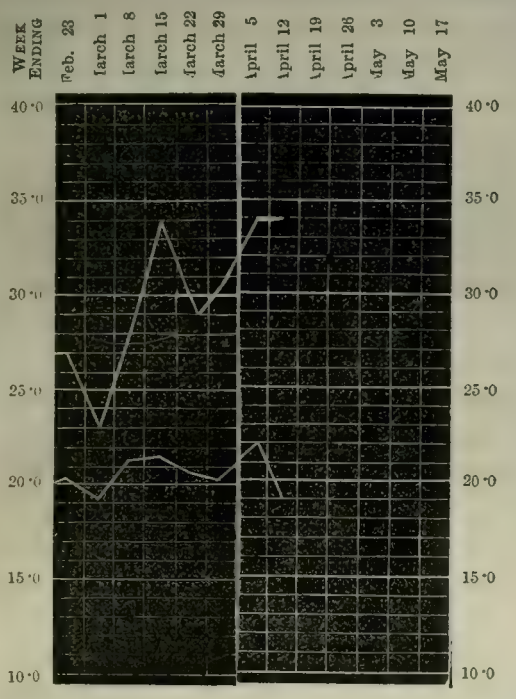
A very thin attendance of members was the not unnatural result of endeavouring to get the Pathological Society to work on Easter Tuesday. The subjects provided for the evening's entertainment were quite up to the average in interest, but an air of languor pervaded the meeting, and was not dispelled by any of the exhibits. The first specimen was one of biliary cirrhosis, by Dr. Turner, in respect of which Dr. Goodhart in vain tried to get an expression of opinion out of the members as to the reality of the existence of this special form of cirrhosis. Dr. Cayley read notes of a case of abscess of the brain, of interest from the point of view of cerebral localisation; and the field of nervous diseases was further illustrated by Dr. Carrington with some cases of cerebro-spinal meningitis. Dr. Tivy related a case of primary cancer of the liver, and Mr. Davies-Colley showed a somewhat rare specimen of congenital tumour of the back. There were a large number of card specimens on view.

In a speech which must be admitted by all to be marked by great moderation, Dr. Rabagliati pointed out, at the meeting of Elementary Teachers at Leeds on Wednesday last, what he believed to be the effects of the present educational system on the physical condition of children. After premising that the tendency of Mr. Forster's Act had been on the whole beneficial, he proceeded to enquire if it had done all the good it might have, and if it had had any results of a hurtful nature. One of the most important and interesting facts which is brought out with great clearness in his paper, is that relating to the mortality from brain disease amongst children at what may be called the school age, *i.e.*, from five to fifteen. During the first ten years that the Act was in operation as compared with the preceding ten years, the general mortality at the above age was reduced by twenty per cent., while the mortality from brain disease remained stationary, and on comparing this group of children with those under five years of age, it appears that since the introduction of the Act the mortality from non-nervous diseases has decreased by one-fifth, whilst that from nervous diseases has relatively increased by one-sixth. This increase was not to be attributed to the greater worry and bustle of modern life, which, contrary to what might have been expected, had hardly produced any effect on the general mortality of adults, nor could it be said that children inherited a greater proclivity to nervous diseases than formerly, as the mortality from this cause in children under five years has diminished rather than increased during the period under consideration. Of the other points dealt with by the author of the paper we cannot now speak, but he may rest assured that he has done good service by his thoughtful and impartial address.

A question of some importance is to be decided in Convocation of Oxford University on Tuesday week, the 29th instant. The statute, which proposes to admit women to some of the Honour Examinations for men, will be considered on that day, and it is said that strenuous opposition will be offered to its adoption. Hitherto the University has examined women through its delegates for local examinations, who have issued certificates to successful candidates. It is found, however, that these certificates, though constituting evidence of high proficiency in the subjects of examination, cannot compare for a moment with the Honours which Cambridge grants, for analogous examinations. Oxford, therefore, runs the risk of losing the share which it has begun to take in the education of the women teachers of England. To obviate this, it is proposed to open to women some of the Honour Examinations for men, but not to grant them degrees; and as in the case of men residence is only required for degrees and not for examinations, it will be dispensed with in the case of women. This would be a great boon to many women, who, for some cause or other, are unable to leave their homes. The movement is supported by the great majority of the teaching body of Oxford, but a strong opposition is threatened by Canon Liddon and others. Mr. Humphry Ward, of 61, Russell-square, will be glad to receive at once the names of those who intend to vote for the statute. It is to be hoped that the enlightened party will score as striking a triumph as they did in the case of the

vivisection vote. After granting animals the privilege of being examined at Oxford, it would be illogical to refuse it to women.

In the 28 great towns of England the general death-rate last week was 20·4, and the zymotic death-rate 3·1 per 1,000. In the 8 principal Scottish towns the general death-rate was 25·2, and the zymotic rate 4·3. The town of Paisley distinguished itself by a general death-rate of 41·0, and a zymotic death-rate of 14·3, due chiefly to the prevalence of measles. In London, as may be seen from the chart, the general death-rate has fallen considerably,



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the last six weeks of last quarter, and the first two weeks of the present quarter.

from 21·9 to 19·1, while the zymotic rate steadily keeps at 3·4. There has been no striking increase of epidemic disease during the week. The number of small-pox patients in the metropolitan hospitals is slowly increasing, and has now mounted to 355, but the deaths last week from the disease were only eight—a fact of some suggestiveness. The deaths from measles and whooping-cough were considerably in excess of the average, on account, no doubt, of lung complications, and were alone sufficient to account for the high zymotic death-rate.

In giving judgment in Mrs. Weldon's successful appeal against the decision of Baron Huddleston, who nonsuited her, Mr. Justice Manisty took precisely the same view, and expressed it in almost the same terms as the opinion previously given in these columns. "If," said the learned Judge, "Dr. Winslow had it at all in his mind that she (the plaintiff) should be taken to his asylum, he ought to have told Mr. Weldon at once, 'I can take no part in these proceedings. I can take no part in obtaining the certificates or getting the order. You must get some one else to act in the matter.' But, at all events, when it was arranged that she should be sent to his asylum he was bound to take no part whatever in the matter. He, however, had instructions from Mr. Weldon to do whatever was necessary in the matter, and was paid thirty guineas for his own fees, and those of the other medical men who were to act in the matter, and whom he himself selected. . . . Now I say unhesitatingly that that was wrong. That the registered proprietor of a lunatic asylum should interfere in any way in selecting the medical men who are to give the certificates, and in getting particulars of the 'statement,' . . . . is most improper." The learned judge then went on to remark upon the method of making the "separate examinations," on which we recently commented, and asked whether that method really satisfied the requisites of the statute that medical men should be absolutely independent, and each exercise an independent judgment, and have nothing to do with the proprietor of the lunatic asylum to which the person is to be sent? The decision of the Divisional Court is an indication of what we should have thought was tolerably obvious, that medical men, as well as other citizens, should not merely act up to the letter of the law, but give a wide and liberal interpretation to its meaning and intention, and not endeavour to sail close to the wind.

Throughout the long-continued agitation for medical reform the good of the public has been put by its promoters in the front rank of the reasons for its urgent and imperative necessity. And during the debates on the present Government Medical Acts' Amendment Bill, as on previous like occasions, the argument, that the public weal demands that the measure shall pass, has been freely employed. We are not at all unwilling to admit that the argument has some real foundation; that it is not a satisfactory or desirable thing that there should be in the United Kingdom nineteen Universities and Corporations legally empowered to grant licences to practise medicine, on conditions varying in breadth and strictness much at the will of the bodies so authorised; and that the inhabitants of Great Britain and Ireland ought to be more satisfactorily protected against imperfectly educated and incompetent medical practitioners. The public themselves ought surely to greatly desire such improved protection. But can it be honestly said that they have ever shown, or do now show, any interest in the matter? Have more than a very few of our legislators even, hereditary or elected, taken any real and active interest in a Medical Acts' Amendment Bill, except politically, that is, according as they were in sympathy with or hostile to the Government that, for the time being, fathered such a measure? He would be a very bold man who would answer either question in the affirmative.

Such a state of things is very unsatisfactory; and very discouraging to all those amongst us who earnestly desire to forward every reasonable improvement in

medical education and qualification, while it affords a rea ly excuse and a kind of justification to those who say that the existing medical systems work admirably well, and that whatever defects exist can be remedied without legislation. We are, therefore, glad to note any sign of interest in matters medical that may be shown by any member of the lay press. Last week one of our evening contemporaries published a note, written by a medical man, pointing out that differences exist as to the interpretation of one of the provisions of Clause 36 of the Medical Bill—a clause that concerns "expenses and medical funds." It has been asserted, the writer states, in an article published in *Blackwood's Magazine* that in future, if the Bill passes, "one class of students, and that presumably the poorer, will be charged a higher fee than another for precisely the same examination in order to provide compensation for certain medical examining bodies who lose their fees in consequence of the new State (Board) examination." One of the medical journals, it is added, promptly denied that this is so, and said it would certainly be unjust if it were the case; while another confirmed the statement made by *Blackwood*.

The provision referred to appears to us perfectly clear; it runs thus:—"In estimating the amount of fees to be charged by each Medical Board for its final examination, a distinction shall be made between so much of the fee as is leviable for the purpose of supplying funds for defraying the administrative expenses of the Board, and so much as is leviable for the purpose of defraying the expenses of the maintenance of museums and libraries; and the fees to be paid by University graduates, or under-graduates holding certificates of having passed the examinations at their University qualifying for admission to the final examination of the Board, shall not exceed the portion of the fee leviable as aforesaid for the purpose of supplying funds for the administrative expenses of the Board." And we fail to see that this provision entails any injustice. As things now are, if a University graduate takes a Corporation diploma, the fee he pays for it goes in part towards the support of that Corporation's museum or library, or both, if any exist: if he does not choose to take such a diploma, he contributes to the support of the library and museum of his University only. But should the Bill become law, the University man will be *obliged* to pass a Board Examination. He will have no choice as to that; but he will have already had to contribute towards the support of the library and museums of his University, and it would surely be very hard on him, not to say unjust, to oblige him, when paying for the obligatory Board Examination, to pay also for the maintenance of the library or museum of a Corporation the diploma of which he may have no intention of taking? Should University graduates wish, in the future, to obtain a diploma from a Corporation in addition to the licence of a Medical Board, they will have to reckon with the Corporations of their choice.

A curious instance of how one book begets another is furnished by the bulky volume of reminiscences just given to the world by Dr. C. J. B. Williams. If certain writers in Dr. Quain's "Dictionary of Medicine," trammelled by the exigencies of space, had not omitted to mention Dr. Williams' valuable contributions to medical science, the incentive required to make him put pen to paper would have been wanting, and the profession would have lost one of the most interesting volumes of medical reminiscences that has been published for years. It is hardly to be desired, however, that every writer who finds his name and work unduly passed over, should sit down and make up for the neglect by writing a book, for we could not expect that the result would in all cases be so satisfactory as in the present one. Dr. Williams has had quite exceptional experience of men and things in his own special line, and can detail it in a happy and interesting manner, without too often diverging into those minor matters of purely personal interest, which spoil most retrospects. A due sense of proportion is not indeed a characteristic of the extremes of life, but we have not much fault to find with Dr. Williams in this respect. His sketches, both with pen and pencil, of the great Frenchmen—La Place, Ampère, Gay-Lussac, Thénard, and Laennec—whom he met in Paris, when studying the newly discovered art of auscultation, are so vivid as to cause regret that he has not rendered a similar service to their English contemporaries. It may be noted with a melancholy interest that these sketches met with the recent approval of the veteran chemist Dumas, who died only a few days ago. We shall, of course, notice Dr. Williams' volume at greater length on a future opportunity.

The gap which has been created in the ranks of men of science by the death, alluded to above, of Jean Baptiste Dumas, full of years and honours, is one not easily to be filled up. By his labours in the vast field of organic chemistry he has made for himself a name which can never die out, even though the work of others may not always confirm his results. No less than forty-four years ago he was elected a foreign member of our Royal Society, and received the Copley Medal of that society forty years since.

The Association for the Advancement of Medicine by Research have added to their series of publications an able and closely reasoned pamphlet on "The Utility and Morality of Vivisection," by Dr. G. Gore, F.R.S., of Birmingham. The author begins by showing the scope and necessity of physiological experiments on animals. He points out that the uncertainty of the results of vivisection—even if admitted—is no bar to their usefulness, for certainty is a relative quality, absolute certainty being rarely attained, even in the simplest sciences. That uncertain and contradictory conclusions are obtained, is but an argument for further experiments, as such conclusions usually arise from imperfect work and insufficient perseverance. The results of properly made experiments do not contradict each other; if they did, successful research would be impossible. The author dwells on and illustrates the fact, that apparently trivial results sometimes lead to the discovery of additional knowledge of the very greatest utility and importance. "The least answer-

able objection to physiological experiments is, not that they are useless, but that the results of them sometimes compel unscientific persons to advance more rapidly, and to change their modes of thought and action. The anticipation that the advance of science will disturb religious belief and emotional sentiment, is largely the essential and hidden cause of opposition to scientific research." In dealing with the morality of vivisection, Dr. Gore points out that the cost in pain and distress of the experimental method of physiology is in many cases vastly less than that of waiting for knowledge from simple observation of natural phenomena. "Whilst we are waiting, millions of men and other animals are suffering pain and dying prematurely." These brief quotations will, we think, suffice to show the tone and method of the pamphlet, both of which are admirable. It deserves careful reading in the profession and outside it.

If the medical men of every considerable city should follow the example recently set by those of Baltimore, and commission one of their number to compile a bulky volume containing a chronology of events connected with the progress of medicine in their special city, and a biography of all the physicians who have practised therein, with a record of their literary contributions, &c., well, the number of crumpled rose-leaves in the bed of a medical editor would be considerably increased. Here and there such a volume may be tolerated, and if every city could find such a painstaking medical annalist as Baltimore has found in Dr. J. R. Quinan, the said medical editor might welcome such an addition to his labours, in view of the help which would concurrently be given to the medical historian of the future. But though every American city is said to regard itself as the hub of the Universe, few could unrol such a blushing record of honours as Baltimore, the physicians of which were amongst the first to introduce inoculation and subsequently vaccination into America, the first in the world to establish a College of Dentistry, the first in the United States to advocate the practicability of ovariotomy, the first in the world to tie the common iliac artery (in 1812), to divide the recti-oculi muscles for strabismus (in 1822), and to successfully perform the Cæsarean operation twice in the same subject, with safety on both occasions to mother and child. Such are only a few of "the donations of the physicians of Baltimore to the profession," and other less go-a-head cities may well hide their diminished heads.

The substance of Dr. Koch's Seventh Report on Cholera may be given in very few words. The connection between localised epidemics of cholera and water-supply from tanks polluted with sewage, had long been recognised by Indian doctors; and Dr. Koch, as soon as he arrived in India, requested the Sanitary Commissioner to inform him at once in the event of the occurrence of such an outbreak. He had to wait some weeks, but at length the expected phenomenon was announced to have occurred in one of the suburbs of Calcutta. At Saheb Bagau, a locality which has been repeatedly visited by cholera during the last hundred years, numerous cases of the disease were reported, and these, on enquiry, were found exclusively in the huts situated round a certain tank. Of the few hundred people (not *one* hundred, as a contemporary has translated it) who dwelt in these huts, as many as seventeen died of cholera, though the disease was not at that time prevalent in the neighbourhood, or indeed in the whole police district of Calcutta. It was proved by the Commission that, as usual in such cases, the dwellers around the tank used it for bathing, and drew thence their drinking water; it was also elicited that the linen of the first fatal case, befouled with cholera dejections, had been washed in the tank. Several specimens of water were taken from different parts of the tank and at different times, and in several of the earlier specimens cholera-bacilli were found in comparatively large numbers, by the aid of cultivation on gelatine. Of the later specimens, taken towards the end of the epidemic, only one contained the bacilli, and that had been drawn from a part of the tank which was especially polluted. Of the whole observation Dr. Koch remarks, "It may be said that chance has thus provided an experiment on the human subject, which makes up for our want of success in the experiments on animals, and which may be regarded as providing further confirmation of the truth of the view, that the specific cholera-bacilli are the actual cause of the disease."

The Commission have also continued their researches in other directions. They have examined twenty fatal cases of cholera *post-mortem*, and the dejections of eleven cholera patients, all of which gave exactly the same results as had been obtained before. They have further been experimenting on the influence of various re-agents, such as corrosive sublimate, carbolic acid and other disinfectants, on the development of cholera-bacilli in cultivation-liquids, and also on the behaviour of the bacilli in carbonic acid gas, and when cut off from the air. Attempts to discover a persistent form of the cholera-bacilli have not met with success, and Dr. Koch concludes that the only way to preserve their vitality for a lengthened period, is to keep them from being dried up. The researches are at an end for the present year. The temperature of Calcutta, in February, had already attained such a degree, that work in the laboratory could only be carried on with the greatest difficulty, and by the beginning of March the heat had become unendurable.

At the last meeting of the Council of the Royal Medical and Chirurgical Society, it was agreed to forward to Her Majesty the Queen a letter of condolence of the death of His Royal Highness the Duke of Albany.

By the death of Mr. Payne, the office of Coroner for the City of London is once more vacant. Without in any way disparaging the late officer, we cannot but feel that the office of Coroner is one which calls for much more medical than legal learning on the part of its holder, and this is especially true in regard to the post now vacant, for the proportion of hospital to other cases is probably larger in the City than in any

of the metropolitan districts. Dr. Wynn Westcott, Deputy-Coroner for Central Middlesex, is already in the field, and we hope shortly to be able to record that the important office of Coroner for the City of London, for Southwark and the Duchy of Lancaster, has been entrusted to him or some other thoroughly capable medical man.

Compulsory sobriety—if it be not absolutely impossible of realisation—is admittedly difficult of attainment. In America, where legislation of this kind has of late moved faster and farther than elsewhere, its progress has developed drawbacks of a kind which could scarcely have been anticipated by its most earnest advocates and supporters; and the thinking men of that country are being brought face to face with "a compensating evil," which deserves the careful consideration of those extreme reformers in this country who aim at laying an embargo upon the sale of all intoxicating beverages. In the first place, it must be recognised that of no article largely used in public consumption—especially if it be an article of diet—can it be asserted that its sale is absolutely "without detriment to the public welfare." And this is a necessity, not of the article itself—which may be perfectly innocent—but of the perverting tendencies of the human consumer. Tallow candles and lucifer matches have contributed in no mean degree to the march of modern civilisation, but the records of the fire insurance companies do not acquit them of all share in the world's disasters; the potato is a sufficiently innocent esculent, but if a man will fill his stomach with whole potatoes, he may have to pay the penalty of death—as was seen in that curious instance of self-indulgence which was reported in London about Christmas-time. Similarly, alcohol, which has its uses, is a substance easily capable of very grave abuse. But, since this substance is inanimate, while human nature is capable of training and education, the real remedy for the evils induced by immoderate indulgence in the one would seem to be most satisfactorily found in a wise culture of the other.

In several districts in the United States the Legislature has attempted absolutely to prohibit the sale of all intoxicants; and a similar law is proposed for other places in the Union. Now, as the editor of the *Century Magazine* has ably pointed out, there is no practical difficulty in applying this prohibition to the sale of *beer* in hotels, bars, drinking saloons, &c., since beer possesses commercial value only as a beverage, and to stop its sale as a beverage is practically to prevent its manufacture. But the case stands otherwise with spirits. Strong solutions of alcohol are recognised requirements in several branches of arts and manufactures; and alcohol would, therefore, continue to be produced and sold—would still be an article of trade—even though the sale of the stronger alcoholic beverages, as such, were put a stop to. Under these circumstances it is difficult to see what effectual guarantee would be given by such a prohibitory law against the simple substitution of spirits for beer amongst such of the population as had any desire for, or any temptations to, the continued consumption of alcoholic liquors.

The beer shops might be closed, and the brewing and malting trades would be ruined; but the distilleries would still be running. And the spirit—sold by the wholesale producers ostensibly for manufacturing purposes—would find its way into the hands of the consumer in various forms, and under various disguises; and that without the possibility of knowing how far, and in what manner, it had suffered adulteration from a dietetic standpoint. The great majority of people would probably be none the worse for a sharp restriction in the amount of intoxicating beverages. But it would be a distinct disadvantage to the community to cut off the supply of lighter intoxicants, such as beer, with the result of substituting the stronger intoxicants, such as whisky—and these probably in a state more or less impure and adulterated.

The probable result of such a substitution (with the exception that in this case the supplanting spirit was genuine and pure) is exemplified in the case of Scotland. Many years ago, roused by the passage of that bill which, in order to give the monopoly to English brewers, practically prohibited the production of Scotch ale, the people resolved, with short-sighted patriotism, to eschew malt-liquor and to adopt the whisky of home manufacture as a beverage in its stead. The consequences are that now, while every Englishman drinks three times as much malt-liquor as the average Scotchman, the Scotchman drinks three times as much whisky as the Englishman drinks of all spirits. And, although the population of the country, which does not equal that of London, is mostly a scattered one, so that there is nothing like the same amount of terrible overcrowding and abject poverty, and grinding competition which, in so many parts of England prove such powerful temptations to drink, yet Scotland is, as all men sorrowfully admit, one of the most intemperate of countries.

A quite different illustration of the inconveniences which may attend coercive legislation of this sort comes to us from Kansas. The laws of that State, we are told, do not allow the prescription of stimulants by physicians except under circumstances of extreme need, and the prescriber has to run the risk of a jury's deciding against him on this point. Recently the following case came before one of the State courts: a person claiming to be ill went to a physician, and, after an examination, a prescription for two bottles of beer was written out. The patient obtained the beer, returned to the physician's office, and then, upon the latter's invitation, the two went to a neighbouring restaurant and regaled themselves upon some oysters and the two bottles of beer, each drinking one. After this they attended a party together, then returned to the doctor's house, and after an hour or two of conversation the patient went home.

At the trial the physician deposed that he had acted in good faith, and believed the beer to be the proper remedy; but the jury found him guilty of a violation of the statute. We could, perhaps, under the circumstances detailed, have scarcely looked for any other verdict; although our sympathies may be with the defendant, and we may believe that the prescription of a bottle of beer—even if repeated *ad nauseam*—would

be probably less harmful than that of the pharmacopœial Mist. Sp. Vin. Gallici *quantum vis.* But from whatever point of view we look at this aspect of the attempt to impose morality by legislation—whether we regard it as implying the possible infliction of a still more serious evil on the people at large, or with reference to the restriction of their personal convenience—calm and thoughtful men will feel but the more reason to endorse the famous dictum of the Bishop of Peterborough, who said that had he to decide between liberty and sobriety, he would choose the former.

It is always humiliating to be obliged to explain one's small attempts at humour, but as several correspondents have been kind enough to inform us that the homœopathic formula is *Similia similibus curentur*, and not *Similes similibus curantur*, which they profess themselves unable to translate, it becomes necessary to enlighten them as to our meaning, and to furnish the clue to the proper translation. *Similes similibus curantur* is a medical rendering of the well-known proverb, "Birds of a feather," &c., "Like doctor, like patient," "Fools go to fools to be cured," "The superstitious are to be found in the consulting-rooms of the superstitious," these and many other free renderings we could supply, any one of which will be found by the reader who cares to refer to our editorial note of last week to sufficiently explain the recondite subtlety of the jest we were then guilty of.

THE CROONIAN LECTURES.

Dr. Hughlings Jackson has once more made the thoughtful student of neurology his grateful debtor. Of the three sets of valuable lectures given this year before the College of Physicians, the Croonians doubtless afford the richest material for most of us to reflect upon. We have profited and been pleased by Dr. Allbutt's eloquence and clinical insight, and have had our mental vision cleared by the careful reasoning of Dr. Andrew; but Dr. Jackson's subject, strange though it be to the minds of many, is illuminated by the scientific use of the imagination; and the more modern forms of thought which he so ably impresses on his clinical material wear almost the aspect of new knowledge. These lectures are so wide and full and suggestive, and touch upon so many points of the first importance in psychology, that no criticism of them can be attempted in the space of a short article. They may be regarded, with certain material exceptions, as mainly a contribution to nervous physiology by a study of pathological examples, and their chief issue may, perhaps, be said to be more concerned with philosophy than with practice. In the light of the doctrine of evolution which, as interpreted by Darwin and Mr. Herbert Spencer, the reader is presupposed to intelligently adopt, Dr. Jackson studies and analyses many phenomena of nervous disease, and no little weight is added by such study to the theory of evolution as applied to nervous physiology. It is, moreover, clearly shown that in many nervous disorders the symptoms are referable, on the one hand, to the modification or abeyance of the highest or most complex parts of the nervous system, and, on the other, to the activity of those parts immediately subordinate to them. The dissolution, thus, of what Dr. Jackson diagrammatically styles the higher or latest developed "layers" of the nervous centres, leaves those on the next lower "level of evolution" to reign predominantly over the rest of the nervous system. This notion is amply illustrated in the lectures before us. As soon, indeed, as the doctrine inculcated by Mr. Herbert Spencer of the evolution of the nervous system, on the structural side, from the simple to the complex—from the more stably to the less stably organised—or, on the functional side, from the automatic to the voluntary, is fully grasped, Dr. Jackson's explication of insanity, epilepsy, and other disorders seems at once to follow as a matter of necessity. None the less, however, is he to be honoured for having usefully applied this key to the matter of nervous pathology. He is, in fact, the skilful and successful employer of the evolutional "calculus" in this confused and confusing study. And if, apart from the philosophical interest of his writings, Dr. Jackson succeeds in helping us to take a truer view of the nature of many nerve-diseases, by introducing some order into the disorder of our knowledge, and giving not only attractiveness but also stimulation to our studies, we are bound to him, even for this alone, no less than if by searching he had found out a new and true bacillus, and perhaps more than if he had discovered a novel remedy for an old disease.

The doctrine of dissolution, or the reversal of the order of evolution, as applied to nerve maladies, is at once fascinating, and completely satisfactory in many cases, and it is no drawback from either of these merits to say that it does not obviously cover all. Generally speaking, as urged once more by Dr. Jackson, when any portion of the nervous system is injured, the parts in connection with it which suffer most are those which are most highly complex and specialised in their functions; for they are at the same time less organised, or, metaphorically speaking, less firmly "set," and are the farthest removed, of course, from automatism. This is evidenced both in the case of spasm and paralysis, and good examples are afforded by the consideration of the ordinary phenomena of hemiplegia, epilepsy, and aphasia. By a process of rigid analogy this notion can be applied to the order and disorder of the highest centres of all; for there is no break in structural continuity from the bottom to the top of the nervous system; and a flood of light is hereby thrown on many of the familiar phenomena of insanity and hysteria. Dr. Jackson ably insists on, and clearly illustrates, the necessary hypothesis that all nerve-centres from the lowest to the highest are sensori-motor in their construction; that the highest "sensory and motor centres" are, in fact, the physical basis of mind or consciousness (though he does not adopt this formula, as we shall see); or, in his own words, if they are for "mind" they are for "body" too. We thus are led to see how even the most complicated organism is in relation with the world external to it, when we learn to regard it, from one point of view, as a complex aggregation of simpler reflex elements excited to action by simpler physical stimuli. The most highly developed nervous system may in this light, in its individual and hereditary constitution, be looked upon as a special reservoir of cosmic force; a subtly made

reflex machine, responding to innumerable and often undiscoverable stimuli, and consisting of a hierarchy of parts, acting in subordination, each higher centre being the co-ordinating or controlling influence over the lower; the highest of all, the co-ordinator of all, or, as it were, the microcosm of the nervous organism.

This view of nervous organisation and disorganisation is apparently the modern philosophical aspect of what has long been implied in the, perhaps, rather vague, phrase of "want of control," as explanatory and illustrative of many nervous disorders. To enter further, however, into considerations such as these would be to go over the whole ground of these lectures, which we hope will soon be obtainable in an independent and, for the sake of the uninitiated especially, a fuller form than that in which they have appeared and were delivered.

The third lecture, where the relation of consciousness to physical nerve-phenomena is considered, is of the greatest interest to all who would study psychology in the light of modern knowledge. Dr. Jackson lays the utmost stress on the importance of using physical terms in describing nervous phenomena, and rightly condemns the employment of the term "sensation," which really has a mental connotation, when all that is meant is an impression conveyed from the periphery towards the centre. His contention, again, that neither "consciousness" nor "unconsciousness"—being terms not of matter but of mind—can be called on to explain physical phenomena is not less forcible because it apparently assumes that this fallacy is somewhat more widely spread than it probably is. Consciousness is admitted by the scientific psychologist to be merely a state attending on the activity of the higher nervous centres, an accompaniment, in other words, of certain nervous efforts. When action becomes automatic, consciousness fades or dies; it comes into play in the upward struggle of the organism to adapt its existence to its surroundings. Now, although this view of the question does not, of course, explain consciousness, it tends to mark the distinction we should endeavour to observe between terms relating to mental and nervous states, and shows us clearly that consciousness can explain nothing. Very complex actions when once they have become automatic, owing to the complete organisation of their nervous structures, are generally admitted to be unattended by consciousness; and the fact of consciousness accompanying certain nervous activities must be noted by the physiologist, but in no way allowed to play any explanatory part. Consciousness, however, we most of us feel, must be correlated in some more dignified way with the activities it accompanies; and at this point Dr. Jackson is to be found outside the pale of science, and companying for a moment with the metaphysicians. In propositions, two of which are almost obvious, and none quite fresh, he lays down (1) that states of mind (or consciousness) are utterly different from nervous states; (2) that for every mental state there is a correlative nervous state; (3) that although the two things occur in parallelism, there is no interference of one with the other. "This may be called," he says, "the doctrine of Concomitance." It certainly may. But why may we not equally well, with Spinoza and Leibnitz, call the doctrine by the older and better known name of "pre-established harmony"? For Leibnitz, seeing much the same difficulty that strikes us now, taught that the body and the mind were two independent but corresponding machines, adjusted like two unconnected clocks, and so constructed that the instant one strikes the hour, the other points it. There is nothing new or very light-reflecting under the metaphysical sun. But by executing over again this little philosophical manœuvre, Dr. Jackson cleverly evades the charge of materialism, and takes up the comfortable position of a Psychological Agnostic.

It is doubtless an error in terminology to say that a volition or emotion can produce a given physical nervous state, as, *e.g.*, that fright can cause chorea; but we do not get much farther, after all, when we say that the nervous activity accompanying the emotion is the cause of the subsequent motor disturbance. It is when we come to study the actions which are least obviously reflex in character, or, to use Dr. Jackson's words, "activities of a centre unprovoked from the periphery," that we arrive at the practical and almost insuperable difficulty of intelligibly expressing the proper relation and sequence of such events as these The most practical lesson, perhaps, to be learned by medical men from these lectures is the dictum, so ably urged by Dr. Jackson, that there is a negative and a positive element in the causation of many morbid nervous phenomena. A positive condition, such as for instance convulsion or over-action, cannot be explained by a destructive lesion of a given nerve-centre. Such a condition is often best explained by the hypothesis of a setting free of previously controlled energies. And here we receive the valuable hint that we should not seek in morbid anatomy a complete unriddling of all clinical phenomena; and find a useful light thrown on many of the events of so-called "functional" diseases, as exemplified by hysteria and the various expressions of insanity. In a series of papers by Dr. Mercier, published in the *Journal of Mental Science*, the scientific interpretation of the higher nerve disorders is being further worked out with originality and admirable clearness; and we have good reason to hope that the able guidance of Dr. Jackson in these most difficult and fascinating departments of physiology and medicine will be not unproductive of valuable results to science and humanity.

THE GRIEVANCES OF ARMY MEDICAL OFFICERS.

While it is gratifying to notice the generous recognition accorded to the work of the Army doctors in the recent miniature campaign in the Soudan, compared with the unmerited stigma cast upon them after the Egyptian war, it must not be forgotten by the profession at large, that those of their brethren who have accepted the Queen's commission have still many tangible grievances to complain of. These grievances mainly resolve themselves into two; first, inequality in the distribution of rewards for distinguished service as compared with combatant officers; and secondly, inequality as regards allowance of sick-leave. We have often visited with scorn the querulous com-

plaints of civilian doctors as to the paucity of titles, and other distinctions conferred on the medical profession, and it may at first sight seem inconsistent on our part to lay stress upon the corresponding complaints of army doctors. But the inconsistency is only apparent. The ideal to be aimed at by the medical civilian, is altogether different from that which the army medical officer may properly place before himself. With the exception of those unenviable few who devote themselves to courtly service, and who are always sure of their reward, whoever they may happen to be, the profession has two ideals to strive after: the one, success in scientific research; the other, success, or at any rate the happy consciousness of work conscientiously performed, in the alleviation of the sufferings of the people. In the one case, State rewards are superfluous; in the other, they are unattainable, and in both cases the less thought about them, the better. Scientific enthusiasm, which is a thing to be cherished and fostered as the very life-breath of medicine, is in itself a sufficient *vis a tergo*, without the necessity for introducing any supplemental *vis à fronte* in the allurement and promise of State rewards. The priesthood of science should need no encouragement in the shape of spiritual peerages to keep it closely applied to the bedside and the microscope. The scientific enthusiast explores, "because he must," and it is as absurd to expect to tempt him on with the dazzle of a State reward, as it is to believe that we can improve the linnet-song of the poet by the promise of a seat in the Upper Chamber. The ordinary practitioner, on the other hand, has no hope of distinction, and must always find his sole reward in the conscientious performance of his daily work. To place any other ideal before him, to turn his eyes to the coloured buttons which so plentifully deck the coats of his Continental confrères, and to put it into his head that he is a hardly used mortal, is to do him an evil service, and to substitute a vulgar and unattainable idea for an honourable one. With army medical officers the case is quite otherwise. Distinctions form a recognised part of their reward. Their ranks are recruited from a very different class of men from those who follow medicine as a science, and the dangers to which they are exposed are very much in excess of those that threaten the ordinary practitioner. A different kind of excellence is rightly demanded of the army medical officer, from that required of the scientific physician or surgeon. There is little room for the scientific ideal in an army doctor's ambition. Courage, activity, physical vigour and endurance, and administrative skill—which last is almost as rare and admirable a gift as scientific power—are the qualities that the War Office properly looks for in those whom it delights (?) to honour. Men with such gifts are naturally and blamelessly attracted by the prospect of State distinction, and the traditions of the service properly encourage them to work for it. There is little hope of reward in other directions. They are mostly cut off, both by their own mental constitution and by the conditions of their work, from the silent rewards of science, and their pay is not magnificent enough to put them even on a level with the country practitioner. Their grievance, therefore, in being treated less liberally in the matter of rewards and sick-leave than their combatant fellow-officers, is undeniably a just one, if it can be proved.

Can it be proved? The following statement of facts will go some way towards demonstration. We will confine ourselves entirely to the campaigns of the last few years. In the operations in Afghanistan, though many medical officers greatly distinguished themselves, and were highly praised in the despatches, their services were entirely unrecognised in respect to promotion. Of these Surgeon-Major Preston, Surgeon Hull, and Surgeon Duncan distinguished themselves in action, while the following were recorded as having suffered severely from exposure and from cholera, viz., Brigade-Surgeon Porter, Surgeons-Major Wright, Wallace, Atkins, Evatt, and Ruttledge, and Surgeons Harrison and Boulton. Surgeon Le Grand was specially mentioned for his services in the cholera epidemic. It is still constantly averred as a reason why army medical officers have less claim to promotion than combatant officers, that they are less exposed to danger; but whatever force there may once have been in this plea, has been entirely dissipated by the change in the modern conditions of warfare. This especially comes out in the records of the South African campaigns. Surgeon-Major Shepherd and two civil surgeons, serving temporarily in the Army Medical Department, were killed in the Zulu War, and Surgeon Longfield, R.N., was wounded. In the same operations, we may add, Surgeon-Major Reynolds especially distinguished himself for personal bravery, but the Victoria Cross was only conferred on him after strong pressure had been applied by his University; while in the operations against the Boers excellent service was rendered by the Army Medical Officers doing duty with the beleaguered garrisons in the Transvaal; but it appears to have been officially unrecognised. The dangers to which medical officers are exposed is here again shown in the list of fatalities, which included Surgeon-Major Cornish and Surgeon Landon, killed at Majuba Hill while attending the wounded. Surgeon-Major Babington was mentioned in both Houses of Parliament, as having worked day and night in succouring the wounded after the disasters, but no other distinction was accorded him. Surgeon Ring and Surgeon M'Gann were also reported as having been in attendance on the wounded under the heaviest fire—the one at Laing's Nek and Majuba, and the other at Ingogo, and yet their valuable and perilous services passed entirely without reward.

In the Egyptian campaign, Surgeon-Major Shaw, it will be remembered, was killed while in the performance of his duties, while Brigade-Surgeon Veale, Surgeon-Major Warren, Surgeon Ray, commanding No. 1 Bearer Company, and Surgeons Prendergast and Kelsall were all reported as having done excellent work. It is true that promotion was freely given after the Egyptian campaign, but we find that for every step accorded to the Army Medical Department, there were two accorded to *regimental* officers, whilst, if the promotions of staff officers were included, the disproportion in the promotions would be much greater. The recent operations, in which the services

of the army medical officers have been fully recognised by the General in Command, have again shown that the dangers to which such officers are exposed are quite as great as those which menace combatant officers. At Teb, Surgeon Martin, R.N., and Surgeon Turner, and at Tamasi, Surgeon Prendergast and Surgeon Cross, R.N., were wounded. In this campaign there was no breakdown in the department, such as was alleged to have occurred in Egypt, and Surgeon-Major McDowell has been especially mentioned as having fulfilled his responsible duties with the highest efficiency. It is very evident from the above bald statement of facts, viz., that the medical officers of the army are distinctly neglected in the distribution of rewards, though their services are quite as important and responsible as those of combatant officers, and their exposure to danger quite as great.

The second main grievance of army medical officers is their unfair treatment in regard to allowance of sick-leave. When a combatant officer falls ill, he can obtain a year or more of sick-leave. The medical officer, on the other hand, though far more liable to contract disease while in the execution of his duty, is only allowed leave for six months, and if he is not then able to return to his duties, he is placed on half-pay. There is a manifest injustice here. The medical officers have more foreign service in unhealthy climates than any other officers, and it is just at the most unhealthy season that their work becomes the hardest. They are thus kept at their posts when combatant officers are able to go away to the hills, and it is hardly to be wondered at, that an excessive proportion of them fall ill. They ought, in fact, to be treated more liberally in the matter of sick-leave than other officers, but the cases of hardship that are constantly being brought to one's attention, show, we fear, that the War Office thinks otherwise.

Over and over again, before now, a strong case has been made out for reform in the points we have alluded to, but reform still lingers. It is not much that is asked for. The following four concessions would probably satisfy every complaint. First, let the title of non-combatant be abolished. It has been shown to be a misnomer, and if it were removed, there would be some likelihood of a more equal distribution of rewards. If it is argued that rewards are kept for personal prowess, then the answer is obvious, for personal prowess is shown quite as much, if not more, in tending the wounded under a heavy fire, as in actually engaging with the enemy. Hand-to-hand fighting is rare in battles between civilised nations, and recent events have shown that in irregular warfare the medical officer is quite as likely to find himself in the thick of it, as the combatant officer. The second reform should be the institution of a rank amongst the medical officers equivalent to brevet amongst combatant officers. At present the promotion for distinguished service of a medical officer is necessarily made at the expense of a brother officer, the higher ranks in the medical department being limited. Thirdly, good work in connection with epidemics, and especially in the case of cholera, should be recognised as giving a claim to promotion; and fourthly, the medical officers should be placed on exactly the same conditions as the combatant officers in the matter of sick-leave. We do not say that these reforms alone would be sufficient to remove all grievances on the part of army medical officers, but if at the same time, a more generous spirit were systematically shown to the department by the War Office, we would venture to prophesy that little more would be heard of these long-standing complaints.

THE GILBERT SCOTT CASE.

The Commission in Lunacy for the trial of the petition concerning the sanity of Mr. G. Scott, has been one of the most momentous events in the legal history of insanity that has happened for many years. Not only is it the first enquiry that has yet been held since the passing of the Act in 1862, but it is rendered memorable by many inherent characters, by the novelty and importance of the points raised and decided, by the admirable summing up of the learned judge who tried the case, Mr. Justice Denman, and by the promptness and unanimity with which the verdict was found. It was admitted by both sides that in July last Mr. Scott was insane. The petitioners, Mr. Scott's wife and brother, maintained that he was still insane and incapable of managing his affairs. On the other hand, Mr. Scott's counsel "did not dispute a temporary derangement, but considered that it had arisen only from drinking," and affirmed that at the present time he was sane and able to manage his affairs, in proof of which he called evidence to show that since his outbreak of admitted insanity he had been engaged in his profession as an architect, and had transacted business of a complicated nature with skill and success. The first part of this defence is of a very surprising character. It virtually enunciate the doctrine that madness is not madness if it is caused by drink. If this defence were valid, any raging maniac might take a knife and run amuck amongst his friends and neighbours, and no step could be taken to restrain him because his madness might be due to drink. Any medical man who certified him as a lunatic would lay himself open to an action at law. It is satisfactory to find that the vigorous intelligence of the judge brushed aside this absurd plea. "If a man," he told the jury, "through drink, or through excessive erotic passion, or through overwork, or anything else, becomes of unsound mind—it does not matter how he became so—it is none the less unsoundness of mind."

The second contention of the defence, that the subject of the petition was able to conduct his business of architecture successfully, was actually proved. He was shown to have recently drawn up the plans and directed the operations for building a church for the Duke of Norfolk, and the whole of this work had been well and efficiently done; the church, it was said, is greatly admired. The fact that a man can conduct his business successfully is, of course, presumptive evidence of his sanity; but it is not conclusive evidence. Everyone who has had experience of insanity knows that a man may be quite able to conduct his business and yet be insane, but to those who have had no such experience, such a statement is startling, and is usually received with incredulity. It is, there-

fore, much to the credit of the learned judge who tried the case, that he should have taken a broad, comprehensive and scientific view of the matter. In his summing up, he said that "juries had sometimes been led to the conclusion, that if a man is proved capable of doing things connected with his trade or profession, and doing them cleverly, that is sufficient to show him capable of managing his affairs." He (the learned judge) did not think this was so. He thought a man might be able to do all these things perfectly well, and yet be incapable of managing his affairs. When such a large word as "affairs" was used, he should say *it applied to the management of all the affairs of his life, of his wife, his children, and his home, and not to mere matters of business only.* This is unquestionably the true conception of insanity, from the scientific point of view, and it is extremely satisfactory to find that it is also the true conception from the legal point of view.

After this judicial dictum, we hope that we shall never again hear the leading journal demanding the life of some wretched lunatic homicide on the ground that he has been able to attend to his work up to the day of the murder. The bloodthirsty tone of the articles of the *Times* on cases of lunatic homicides is most reprehensible; and if anything could be in worse taste, or display more cynical disregard of the amenities of journalism than its articles upon the Gouldstone case, it is its leader upon the case of Mr. Gilbert Scott. It is difficult to imagine that any human being could be placed in a more painful and distressing position than this unfortunate man's more unfortunate wife. To see the man with whom her life was bound up, her husband, the father of her five children, the bread-winner of her family, attacked by the most cruel infliction to which mankind is subject, to have her own and her children's most sacred feelings outraged by him, to be compelled to separate herself from him, and to be the instrument of his incarceration, and, finally, to be obliged to drag her husband's malady and her own sorrows before the whole world; surely this is suffering enough for any woman. Surely the leading journal of the world, the representative of the cultured classes, will deal tenderly with her. In such circumstances, under such a heavy trial, in so unforeseen and unusual a calamity, a false step, an error of judgment might be looked on with a lenient eye. But she made no false step. She acted, not only with the sanction, but on the advice of her husband's brother and of his intimate friend, an eminent barrister. It is difficult to see what better course she could have taken, even had their advice been bad. But it was not bad. The course taken in getting Mr. Scott placed under supervision and under treatment at the earliest possible moment after his malady had unmistakably declared itself, was the very best, the kindest, the most judicious that could possibly have been taken. As the learned judge put it to the jury in his admirable summing up, "to appeal to the jury on the ground that it would be a cruel or shocking thing to incarcerate Mr. Scott, was to appeal to their prejudices and not to their reasons. It begged the whole question. If a man was of unsound mind, his confinement was necessary. If there was any prospect of his recovery, under proper care, it would rather be a cruelty than otherwise to refuse to confine him." Yet for this poor woman, thus tried and not found wanting, the *Times* has nothing but sneers and inuendoes, and insinuations:—"His family deserve whatever credit is due for promptitude." "It is just conceivable that a little patience might have saved his friends from having to perform the painful duty of locking him up among declared madmen." "Four days of partial (!) derangement seems scarcely strong enough evidence to warrant a step which cannot fail to aggravate the mischief should the diagnosis be mistaken." In other words, the treatment adopted could not fail to make him more mad, supposing that he was not mad at all! Certainly, in this case, the *Times* has not taken up a line which it will be able to look back upon with pride or satisfaction.

REVIEWS AND NOTICES OF BOOKS.

A SCIENTIFIC BLUE-BOOK.[1]

The magnificent second volume of scientific reports, which has recently been issued by the Imperial Board of Health in Germany, is well calculated to arouse envy and discontent in the breast of every scientific Englishman. We cannot forget that we were first in the field with State contributions to science, and that the admirable volumes yearly issued by the Privy Council under the editorship of Mr Simon, have formed the prototype of these splendid publications that come to us from Germany. But we, with all our wealth, have been far outdistanced by the Fatherland, comparatively poor as it is, and no Englishman who has the honour of his country and of science at heart, can see with equanimity another country taking up, and so strikingly improving upon, the beneficient *rôle* which we were the first to initiate. Mr. Herbert Spencer, we suppose, would regard the expenditure of State funds on the advancement of science, as only another link in the chain of "the coming slavery," but the School of Doctrinaire Radicals has had its day, if not its say, and now that the State has elected to take so much upon its shoulders that has hitherto been left to private effort, it is hardly too much to ask that some of the funds which are being so freely spent on the bricks and mortar of museums of art and science, shall be devoted to providing those metaphorical bricks and mortar on which the scientific edifice of the future must be founded. It is a disgrace to England that she almost alone amongst civilised countries has no State-supported institution for scientific research into those abstruse and difficult questions, on the successful solution of which the happiness and health of generations yet unborn must depend. No more remunerative investment could be found, we are sure, than the expenditure of a few thousands yearly on a State laboratory, in which those problems of disease, that are now so largely engaging scientific thought, could be systematically worked out by the best minds of the day. And the volumes of reports issued from such a workshop would, we venture to say, not only be welcomed with proud satisfaction by

[1] "Mittheilungen aus dem Kaiserlichen Gesundheitsamte;" herausgegeben von Dr. Struck, Geheimer Ober-Regierungsrath. Zweiter Band. Berlin: Hirschwald, 1884.

the nation, but would be pointed to by future generations, in the same way that we now point to the noble buildings of the Middle Ages, as glorious evidence of work, done with faithfulness and foresight in the interests of posterity.

The volume under review, which has been issued under the supervision of Dr. Struck, the Director of the Imperial Board of Health in Berlin, will certainly occupy a prominent place amongst the remarkable publications of the present year. If only for the papers which it contains upon the subject of tubercle and tubercular disease the book is of the highest value, and from the fact that part of the work which it records has been carried out by Dr. Koch, as a continuation of his study of the properties of the micro-organism which he discovered and announced to the medical world only two years ago, that value is not only present but also historic in character. The first volume of the series was also largely devoted to the subject of micro-organisms, but it dealt in great measure with the various methods of investigation employed in their discovery. The direct object of the present volume is the study of the causation of certain infectious diseases, and of the best means of checking their spread, by disinfection.

First in position, and probably to most readers first also in importance, stands a paper by Dr. Koch, on the ætiology of tubercle, illustrated by a series of admirably executed plates, from which alone a fund of practical information may be gained. The subject is opened by a historical account of the labours of Klencke, Villemin, Klebs and Cohnheim, in the same field, and a clearly written description of the methods of cultivation, whereby the bacilli are isolated from the material in which they have been at first developed. The chapter following is devoted to the proof of the occurrence of pathogenic organisms in tissues affected with tubercular disease, and in their secretions. The methods of staining are described with precision and distinctness, and it may be noted that after treating his sections with nitric acid, Dr. Koch advises that they be immediately transferred to alcohol, without previous washing in water. The locality of the tubercle-bacillus in the affected tissues and cells is of much importance, and a good deal of space is devoted to the subject; the relation of the bacillus to the nuclei of the giant-cell being minutely described and graphically illustrated in the plates. "One finds them (the bacilli) with the greatest certainty at those spots where the tubercular process has just begun, or is rapidly progressing." In the caseous material there are generally but few to be seen, except where the disintegrating process is taking place very quickly. The bacilli, as Dr. Koch confidently asserts, are the cause, and not the consequence, of the degenerative change. With respect to the process by which a latent tubercular centre is capable of giving rise to an active general infection, he believes that it is due to the agency of the wandering cells (leucocytes) which bear the bacilli about in the tissues, and may leave them in any spot whatsoever, being themselves brought to a standstill by their constantly increasing burden. What the next step in the process may be is at present unsettled, and remains to be determined by future investigations.

The subject of general tuberculosis in the human subject is discussed in the light afforded by the series of practical observations upon acute tuberculosis, tubercular phthisis, and tubercular disease of all the organs in their turn, which Dr. Koch has undertaken. The belief which was at first largely held in this country, viz., that the bacillus was only to be found in the later stages of tubercular formations, will be completely upset by the results here given of investigations into a series of nineteen cases of acute miliary tubercle. "In no single instance were the bacilli found to be absent. The smaller and younger the nodules, the more profuse were the bacilli contained within them, being especially numerous towards the centre." With the beginning of caseation the number of bacilli was found to be diminished. In twenty-nine cases of pulmonary phthisis the bacilli were invariably present, and usually directly proportionate in number to the rapidity of the process of disintegration. Following out the tubercular diseases of animals, through various species, the constant association of this special bacillus with the occurrence of tubercle, is everywhere demonstrated. The isolation and re-cultivation of the micro-organisms, and the results of infection experiments are each in turn considered, and the paper is brought to a close by a critical examination of the results of all the observations therein recorded, in proof of the relation of the bacillus of tubercle to the ætiology of tuberculosis.

A short paper by Dr. Gaffky contains a record of the daily fluctuations observed in the number of bacilli present in the sputa of fourteen patients, suffering from tubercular phthisis. Of 982 observations, only forty-four failed to demonstrate the presence of the micro-organisms. The subject of the "Disinfection of Phthisical Sputa" is discussed by Drs. Ernest Schill and Bernhard Fischer. The infective power of such sputa is at first equally manifest in the fresh moist secretion, and in the dry dust into which it may, in course of time, be converted. Unlike certain other bacteria-bearing matters, the tubercular tissue appears to lose its infective power after a lapse of time; dried sputa, which appeared active at the 95th day, gradually became less powerful, until on the 226th day they produced no effect whatever. A long and laborious series of experiments are here recorded, and the results obtained by the various disinfecting agents, duly tabulated. The list of contributions, each containing the results of many months of original research and experiment, which is contained in the volume, is too extended to admit of special reference to the vast number of new and interesting observations brought forward. Many of them, dealing with such subjects as the presence of micro-organisms in atmospheric air, their effect upon the air-passages of the body, and the means of lessening those effects; the ætiology of typhoid fever and of diphtheria in relation to the presence of bacteria; disinfection by chlorine and bromine, &c., must be deferred for separate consideration, as it is our intention to publish a series of abstracts of the more important articles. The work, as a whole, is admirably arranged, the printing and the illustrations being executed in a manner which leaves little to be desired.

St. Thomas's Hospital Reports; New Series, Vol. xii. for 1882. London: J. and A. Churchill.—This volume was very late in appearing, though not quite so late as the date of this notice might lead the reader to suppose. The major part of it is taken up by the reports of the medical and surgical registrars, and of the ophthalmic, obstetrical, and throat departments; the last-named, by Dr. Semon, certainly justifies the formation of a special department, and contains an account of many interesting cases, which, under other circumstances, would probably have been overlooked. We have only space to allude to one of these cases now, and we select it on account of its extreme rarity; the case was one of so-called aphonia spastica, or spasm of the tensors of the vocal cords in a seafaring man, æt. 57. Dr. Semon was able to examine him and recognise that during the spasmodic closure of the glottis on phonation, the vocal cords seemed almost to overlap one another. As is frequently the case with patients of exceptional interest, the man was not seen a second time. The 150 pages devoted to original papers are mainly occupied by the physicians. Dr. Bristowe contributes a paper on painful paraplegia, being a study of six cases of cancerous or sarcomatous disease of some part of the spine. Dr. Stone writes on "some effects of brain disturbance on the handwriting," in which he describes a curious cerebral attack he had himself undergone, during convalescence from which he had what he considers to have been a "diplographia depending on want of synchronism or parallelism between the two hemispheres of the brain." "On some clinical aspects of glycosuria" is the title of a paper by Dr. Ord, in which he treats of glycosuria as a symptom apart from diabetes mellitus, and as occurring in association with certain nerve disorders, with gout, with errors of diet, and with albuminuria. Though by no means an exhaustive article, it is a distinct addition to the literature of an important topic by one well qualified to write upon it. Dr. John Harley advocates boldness in the treatment of hydatid tumours of the liver; he taps with a large trocar and canula, and makes a permanent opening by tying the canula in. At the end of a week the cyst should be adherent to the abdominal wall; he then removes the lining membrane of the cyst wall piecemeal by sucking it up into the eye of a catheter, and then tearing it away; when all the membrane has been removed, the cavity contracts and becomes obliterated. Mr. Le Gros Clark contributes a chatty article on a great variety of diseases, the outcome of the experience of a long career, which will be read with interest and pleasure by all his former pupils. Mr. Croft concludes a short paper on the treatment of cancerous obstruction of the œsophagus by permanent catheterism with a series of propositions to the effect that the operation is a safe one in moderately early cases, that it is not intrinsically dangerous, that it may be performed where gastrostomy would be certain to fail, and with more immediate beneficial results, that it may be continued indefinitely so long as the patient lives, and that with due care the risks are but few. The other papers are, on two cases of ulcerative endocarditis following an attack of acute pneumonia, by Dr. Gulliver; on paraplegic rigidity in hemiplegia, by Dr. Hadden; on a case of fatal hæmorrhage from the internal carotid after suppurative tonsillitis by Mr. Pitts; a case of spontaneous gangrene of the toe, by Mr. Makins; one of paralysis of the serratus magnus, by Mr. Clutton; and two cases of pemphigus, by Dr. Payne. The space at our disposal does not permit us to consider these in detail, though there is much that is of interest in many of them; but we must not omit to mention in conclusion a brief obituary of the late Dr. Twining by one of the editors.

Simple Chronic Peritonitis with Effusion; by Dr. H. Vierordt. Tübingen: H. Laupp, 1884.—To determine the pathological changes which are taking place in processes of disease which invariably end in recovery, is one of the most difficult of the problems that have to be solved in the study of medicine. It is only by applying the rules of analogy that the nature of the phenomena occurring in hidden cavities can be even approximately discovered, and this very means is so beset by possible sources of error, that, in some instances, the difficulties of diagnosis have led to a kind of nihilistic despair, and authors have found it easier to deny the existence of some pathological conditions altogether, than to explain them from the symptoms alone. The subject of Dr. Vierordt's monograph may be regarded as an instance of this. Chronic peritonitis is, in the vast number of cases, a secondary condition, of which the primary cause is to be found in specific deposits in the peritonæum itself, or in some definite disease of some of the abdominal viscera; but cases occasionally present themselves in which none of these causes are present, and the only explanation of them must be sought in a simple inflammatory condition of the membrane itself. Such a condition, however, has been frequently denied; and, amongst others, by Dr. Felix von Niemeyer. In the present work we have an accurate clinical record of 28 cases of simple peritonitis, followed by a careful account of the disease, its ætiology, course and treatment, partly derived from a close study of the recorded cases and partly argumentative, in criticism of, and reply to, the writings and opinions of other workers in the same field. The importance of watching the indications afforded by the urine in these cases is more than once insisted upon. The author shows that not only do fluctuations in the quantity and density of the urine take place with the varying increase and decrease of the peritonæal fluid, but that the success of certain lines of treatment, intended to promote absorption, may be accurately gauged by observation of the signs afforded by the urine. The disease, although assumed to be a simple inflammation at the outset, is prone to be followed by other and often more grave affections of the peritonæum; and the gravity of each particular case is, therefore, dependent upon it freedom or otherwise from complications. In this respect the affection offers a striking contrast to the analogous process in the pleura, in which the simple forms of inflammation are common and in themselves serious, whilst specific deposits in the membrane are comparatively rare. This question, of what might be called the inherent tendency of the various serous membranes to become attacked by different forms of disease, is only lightly touched upon by Dr. Vierordt; nor does he do more than mention the occasional occurrence of simultaneous dropsy of all the membranes. In his account of the treatment of simple peritonitis, he lays especial stress on the value of mercurial inunctions, and other local applications, but is somewhat meagre in his account of the operation of tapping. The monograph, as a whole, is a useful contribution to the literature of a subject already well discussed, but by no means thoroughly exhausted.

Révue Mensuelle de Laryngologie, d'Otologie, et de Rhinologie. Nos. 1 and 2, 1884.—An elaborate dissertation on the phenomena and causation of hiccough, by Dr. Délie, d'Ypres, opens the first number of this year's issue. The object of the author is to call especial attention to the pharyngo-laryngeal symptoms which may accompany this troublesome affection, setting aside for the time the accepted theories with respect to the influence of the phrenic nerve in its production. The starting point in his investigations was furnished, he tells us, by those cases in which spasm of the vocal cords takes place, after local applications to the larynx, accompanied by a painful constriction of the epigastrium, both of which are at once relieved by the occurrence of noisy and voluminous eructations. Details are given of several cases in which obstinate hiccough was found to be due to some pharyngeal, laryngeal or tracheal irritation. A case of hiccough and pharyngo-laryngeal spasm is related with great accuracy of detail, the whole affection being due to hysteria, and accompanied by a great variety of symptoms. From a therapeutic point of view, however, it appeared that local mechanical applications to the pharynx itself only sufficed to check the hiccough even for a few moments, the spasm returning with the cessation of the treatment. Relief was, however, ultimately obtained under bromide of potassium. Arguing by the light of his clinical observations alone, Dr. Délie assumes that hiccough results from direct or reflex irritation of the spinal accessory nerve, and manifests itself by spasm of all the muscles supplied by this nerve or by its anastomoses. An interesting case of probable fracture of the auditory ossicles from indirect violence, is

communicated by Dr. E. J. Moure. The commencement of a paper on syphilis of the ear, in the February number of the *Revue*, is interesting from a historical standpoint. A case of epithelioma of the posterior part of the cricoid cartilage, extending into the pharynx and upper part of œsophagus, is related by Dr. G. Coupard, by whom the growth was destroyed by means of the galvano-cautery at a moderate heat, in several sittings. The chief, and at first the only, symptom produced by the tumour was an unaccountable difficulty in swallowing bread. After four months apparent freedom, the growth returned, the glands became infected and the patient rapidly sank, with all the symptoms of a cancerous cachexia. A case of what he terms scotoma of audition is published by Dr. Brunschvig. The patient, a plumber, with slight catarrh of the middle ear, was discovered to be quite deaf to sounds produced at certain distances, although well able to distinguish the same sounds when brought within, or placed beyond, the same ranges. The observation was only made on two occasions, but the results were confirmatory.

Nordiskt Medicinskt Arkiv. Band XV., third and fourth parts, 1883.—Amongst many interesting original articles in the last two volumes of this quarterly journal, the following may be specially noted. Dr. Warfvinge, of Stockholm, discusses the antiseptic treatment of infectious disease in general, and of typhoid fever in particular, from what may be termed a "bacterial" standpoint. Regarding the presence and development of lowly organisms as the essential and primary cause of the occurrence and continuance of the infective fevers, he would act in accordance with his convictions and attack the fever by attempting to destroy, or at least neutralise, the activity of the parasites which maintain it. He claims to have obtained satisfactory results in typhoid fever by means of the internal administration of carbolic acid, the temperature generally being considerably lowered, and other symptoms materially improved. His belief in the virtue of specific remedies is apparently of no ordinary kind, extending as it does to a trusting faith in the curative action of alum in whooping-cough. Contrary to the experience of other observers, he has found that the internal administration of carbolic acid does not produce reduction of temperature in healthy persons. Dr. E. Bull, of Christiania, contributes a paper on operative treatment of lung diseases. Several operations have been attempted for the permanent closure or contraction of large pulmonary cavities, but the results can hardly be yet considered encouraging. He relates particulars of one case, unsuccessful owing to a mistaken diagnosis of the nature and seat of the lesion, and points out the liability which is always present of physical signs being misinterpreted even by the most skilled observers. Dr. Ödmansson, of Stockholm, gives, at considerable length, his clinical experience and views on the subject of the excision of primary syphilitic sores. His results go far to prove that the free removal of the primary sore has a marked influence upon the subsequent development of the disease. In almost all his cases there had been already some enlargement of lymphatic glands, but, notwithstanding this fact, the subsequent phenomena were confined to the very mildest secondary signs, and in no instance followed by any grave lesions of any of the tissues. The method of excision was simple and free, ordinary curved scissors being used. A paper by Dr. Georges Asp, of Helsingfors, on the development of end-organs in nerves; and some clinical observations on meningitis in very young children, by Dr. O. Medin, of Stockholm, are also of interest.

The Diagnosis of Diseases of the Spinal Cord; by W. R. Gowers, M.D. Third Edition. London: J. & A. Churchill, 1884.—This little work well deserves the success it has met with, for it gives in a clear and succinct manner, every hint that up to the present time can be made available to aid in determining the nature of the complex group of symptoms, owning for their cause some disturbance in the spinal cord. The present edition is enriched by a few pages on the means of distinguishing between functional and organic disease, which, as every one must have often experienced, is sometimes a very real difficulty.

ABSTRACTS AND EXTRACTS.

THE SUMMING UP IN THE GILBERT SCOTT CASE.

The principles laid down by Mr. Justice Denman in his summing up in the Gilbert Scott case are so important in a medico-legal point of view that we need make no apology for republishing the *Times'* report of it.

His lordship commenced by reviewing the circumstances which led to the passing of the Act of 1862, under which this enquiry was held. After reading the words of the Act, his lordship said that the question for the jury was whether Mr. Scott was of unsound mind, and incapable of managing himself or his affairs. In order to elucidate those words, his lordship read several passages from "Blackstone's Commentaries," in definition of the term "lunatic," and in reference to the legal position of those found lunatic by inquisition. On that his lordship said to appeal to the jury, on the ground that it would be a cruel or shocking thing to incarcerate Mr. Scott was, to appeal to their prejudices and not to their reason. It begged the whole question. If a man was of unsound man his confinement was necessary. If there was any prospect of his recovery under proper care, it would be rather a cruelty than otherwise to refuse to confine him. Juries had sometimes been led to the conclusion that if a man is proved capable of doing things connected with his trade or profession, and doing them cleverly, that is sufficient to show him capable of managing his affairs. He (the learned judge) did not think this was so. He thought a man might be able to do all these things perfectly well and yet be incapable of managing his affairs. When such a large word as "affairs" was used, he should say it applied to the management of all the affairs of his life, of his wife, his children, and his home, and not to mere matters of business only. As to managing himself, it was clearly not evidence of insanity that a man is fond of drink. But if, coupled with other acts, which a jury might reasonably look upon as mad acts, there should appear an inability to control himself on occasions when it was of the utmost importance that he should control himself, that would be evidence. And if a man, through drink, or through excessive erotic passion, or through overwork, or anything else, becomes of unsound mind—it does not matter how he became so—it is none the less unsoundness of mind. It should be understood that in every case the presumption was in favour of sanity. A man must be taken to be sane until he is shown to be the contrary. But if a man was proved to be insane in June, and again in July, August, and September, and so on in each following month, and was then tried for murder in April, he (the learned Judge) would never tell the jury that it was necessary still to presume sanity as though the contrary had never been shown. If insanity had been established and had gone on for some time, then, in spite of the legal presumption, a different state of things would be raised in the minds of those who, as reasonable men, had to judge of what followed. What was the general character of the man before all this took place? The account given of him before last year might have been overcoloured. But it would be a question for them (the jury) whether the person they had seen there was not prior to 1883 a man of singularly good appearance, manners, morals, and all such things. That being the previous character of the man, they came to the date in 1881 when he brought out his architectural work. Before that time all they knew was that he had been at Eton and at Cambridge, had obtained a first-class in the Moral Science Tripos, had then taken to architecture, and no doubt succeeded his father in some of his work. Then he published his book, and about that time his wife noticed that he became excited and irritable, and was taking spirits. But, she said, he became all right again. Then we came to the visit to Wimbledon in July, 1883. (His lordship then referred to the events of July 16–20, remarking that though at first it was doubtful whether

he was suffering at this time from anything more than the effects of a series of drinking bouts, as the case went on it became indubitable that he was completely out of his mind and suffering from delusions.) A question had been suggested whether it was a wise thing to send him to Bethlem. Bethlem had, no doubt, an ugly name. At the same time, when it was suggested that there was some sinister motive in what was done, they had it sworn to that it was done on medical advice, and that the doctor who was consulted thought it was the best place for Mr. Scott. At the time he was in Bethlem it might be presumed he was looked after and his mind properly cared for. At this time he wrote letters to his wife and other people. There could be no doubt from these that down to the end of August his delusions continued. His lordship went through these letters at length, noticing his suspicion of designs against him, of the "doctoring" of cigars sent him, of his wife's fidelity, and his declarations of the sanity of the whole of Bethlem. After these his lordship read the principal letters from Rouen. Referring to the threatening post-cards to Mr. Dunkenfield Scott and Mr. Webster, his lordship said this was an act which brought him within the reach of the criminal law. Would a jury at that time have convicted Mr. Scott of threatening to murder, or would they have found that he was at that time in such a state of mind that he did not understand the quality of the act he was doing? Were these sane or insane acts, and was the man at that time in a fit state to have the management of himself or his affairs? His lordship then went at great length into the correspondence from this point down to the post-card written to Mr. Justice Day, and read the previous morning, which his lordship said was undoubtedly a very extraordinary act, though whether it was due to insanity or mere eccentricity it was for the jury to say. Turning to the evidence of the medical men, the learned judge said that as a matter of course they would find the medical men differing in opinion. On questions of fact, as to the habits and behaviour of lunatics, they might be trustworthy guides. After all, the medical men were only men of common sense, and the jury were equally men of common sense, and though it was almost impossible for a layman to say why he thinks, or does not think, a particular man of unsound mind, the opinion of laymen on such questions was often a matter of complete certainty. Doctors differed, engineers differed, and experts generally differed, and in giving evidence they naturally tried to make a case for the side by which they were called. His lordship then proceeded to read in detail the principal evidence of the witnesses on both sides. Having done this, his lordship said it was for the jury to say whether this gentleman is at the present time, at the time of the conclusion of this enquiry, of sound mind, that is to say, a person capable of managing himself, of keeping himself from doing unworthy acts, or perhaps dangerous acts, or a person capable of managing his own business, in the sense not merely of possessing first-rate professional ability, but of being one who could properly and safely be left to himself to control all that concerned himself. Or, on the other hand, it was for them to say whether he was a person who ought to be put under the care of others, that is to say, under the care of the Lord Chancellor, for the proper protection of himself, and his estate, and those connected with him. In conclusion, his lordship told the jury that a unanimous verdict was most desirable, but, as he had informed them at the outset, the law provided that the issue might be decided by the verdict of the majority. He, therefore, requested them to take a reasonable time with the view of securing unanimity, but if after reasonable consideration they found that only a majority could agree either way, it would be his duty to report accordingly.

PHARMACOLOGY AND THERAPEUTICS.

PARALDEHYDE AS A NARCOTIC.—Dr. Carl von Noorden, of Giessen, in an article on this subject, states that paraldehyde was first recommended as a narcotic by Cirullo, in consequence of experiments made on animals; he found that it produced in them a quiet sleep without any excitement and followed by no ill effects, and that it had no disturbing influence on the heart or respiration. Most of the notices hitherto published on the effects of paraldehyde on men have been from various lunatic asylums, and all have been favourable. The paper by Dr. von Noorden gives the results of the use of paraldehyde as a narcotic in a general hospital on all classes of patients. The paraldehyde used was obtained from E. Schering, of Berlin, and Merk, of Darmstadt, the dose varied from three to six grains, usually given with equal quantities of Tinct. Aurant Co. and Syrup; generally four and a half grains were sufficient, but when larger quantities were given no unpleasant results followed. The drug was usually given at eight p.m., sleep followed, as a rule, in about 30 minutes (from 15 to 45), and there were very rarely any complaints of nausea after taking it. The patients slept, as a rule, from five to six hours, the sleep was quiet and deep, and if from any noise, &c., the patients woke up, they soon slept again. Those patients who suffered merely from nervous sleeplessness generally slept quietly through the night, others who required a narcotic on account of dyspnœa, cough, or pain, were generally wakened towards morning by their complaint, and prevented by it from again falling asleep. On waking they felt refreshed, and had no bad after-effects, but sometimes noticed a smell and taste of paraldehyde, which, however, was only strong enough to be disagreeable in two cases. The drug was given about 120 times to 30 different patients, most of them only took it once, several often; but these latter alternately with morphia, opium, bromide of potassium and cannabin, in order to compare the effects of these various narcotics. It was given in cases of emphysema, bronchitis, phthisis, myocarditis, valvular diseases of the heart, spinal and other nervous affections, later stages of pneumonia, jaundice, chronic articular rheumatism and sleeplessness from rheumatic neuralgia, &c. In two cases it produced nausea and headache, probably from individual peculiarities. In cases of severe gastric disorder and laryngeal phthisis it cannot be given, owing to its local effects. Special attention was given to its influence on the organs of respiration and circulation, both in cases where these organs were diseased and where they were healthy. Respiration was not affected in any case. Patients with weak hearts bore the drug well, experienced but little diminution of arterial tension, and obtained refreshing sleep. To observe the influence of paraldehyde by day, four patients took it in doses of five grains, all had slept well the previous night and only transitory sleep was produced; in these also the respiration was not influenced, there was a slight diminution in the frequency of the pulse, and a slight diminution of arterial blood-pressure. In order to determine the arterial tension, this was estimated by a sphygmograph at short intervals, both before and after taking the drug. Three of the four were strong men with healthy hearts, in these there was a slight decrease of tension. The fourth suffered from mitral insufficiency and constriction, and for a long time had been near the stage of failing compensation; in him diminution of tension was almost absent, and the drug had less influence in this direction than in the three with healthy hearts. The decrease of tension reached its maximum from one to two and a half hours after taking the paraldehyde; half an hour after this had been reached, the tension was in all cases restored to its previous height, and a few hours later had quite regained it. These cases appear to show that paraldehyde may safely be given as a narcotic in cases of heart disease where chloral would be dangerous.—*Centralblatt für Klinische Medicin*, No. 12, 1884.

COMPARATIVE EFFECTS OF PARALDEHYDE, CHLORAL, AND MORPHIA.—Dr. Dujardin-Beaumetz publishes in the *Bulletin de Thérapeutique* (January 30th), the results of numerous trials which he has made of paraldehyde, according to M. Yvon's formula, viz., paraldehyde, twenty parts by weight, alcohol at 90° 100, syrup 75, and tincture of vanilla 5 parts. Of this solution twenty to thirty grammes (*i.e.*, two or three of paraldehyde) are given at a dose. All patients agree as to its having a less disagreeable taste than chloral, while a calm and refreshing sleep of from four to eight hours is soon produced, preceded in some cases, and especially in females, by a few minutes of excitement. On awaking there is no

headache or heaviness. There is, however, an extremely strong odour of aldehyde exhaled by the breath, especially when three grammes have been taken. As a hypnotic, it has proved itself superior to morphia and chloral; the sleep produced being more calm, waking being also more easy, and unaccompanied by the pains in the head, attendant upon opium. But while chloral, and especially morphia, will allay pain without causing sleep, this is not the case with paraldehyde, which under these circumstances is powerless. It is, however, an excellent remedy in insomnia, and that even in cases of morphiomania; its use in such a case, in the hands of Dr. Constantin Paul, having broken through the morphia-habit. It has yet to be determined whether the prolonged use of this substance may not induce disorders in the economy, analogous to those produced by alcohol, and further the stability of a substance which is an intermediate between alcohol and acetic acid, with a tendency to return to one or other of these bodies, has to be enquired into.

Desiccated Ox-Blood.—Dr. Stewart, of Philadelphia, observes (*Medical Reporter*, January 26th), that in the last edition of the *United States Pharmacopœia*, he is credited with the introduction of desiccated ox-blood, as a method of administering iron, but he wishes to state that this is neither the sole, nor even the principal use of this valuable article. It is, in fact, a concentrated nutritive tonic, prepared by drying bullock's blood at a low temperature, in shallow pans, so as to prevent the albumen coagulating. The product is in the form of thin scales. The blood may be prevented from clotting by stirring it before drying, and removing the small portion of fibrin that attaches itself to the stirring rod, or by adding a small portion of acid before desiccating. So prepared, blood has been used with benefit in wasting diseases; in various cachexiæ, such as scrofula, consumption, and syphilis; in anæmia and chlorosis, in atonic dyspepsia, after hæmorrhages and exhausting discharges; in the height of the fever process; in convalescence from fever; and as a "building-up" measure in surgical cases before or after operation. It is also indicated whenever it is desirable to give iron, but more especially, whenever the problem is to give food. If quickly dried, it is inodorous, and almost devoid of unpleasant taste. It may be prescribed with glycerine and brandy, or simply in solution in water. A good formula is, Sanguinis exsicc. ʒvi, Aquæ ʒiv, Misce et adde Sp. Vini Gall., Glycerini aa.ʒj. A tablespoonful three or four times a day. In fever cases, when the temperature is high, a teaspoonful, or more if the stomach will bear it, may be given every hour, the dejections being carefully examined, to see whether it is all assimilated. When it is not, they are stained black, but the addition of pepsin will usually remove the difficulty. A few drops of any essential oil will effectually disguise the taste. When an aqueous solution of the blood is prepared, the water must never be poured on the scales, but the scales placed in the water, stirring with a glass rod, or spatula, so as to prevent their agglomerating into a mass. The water used also must be always cold, in order to avoid coagulating the abundant albumen. Administered by the rectum, the blood is in some instances absorbed, but in others it is not so, and in these last, the addition of pepsin should be tried. Before injecting the solution, it should be only gently warmed, so as to avoid coagulation of the albumen, which occurs at 160°.

Effects of Tobacco-Smoking on the Eyes.—In a discussion which took place at the Paris Société de Médecine Publique, on the accidents produced by tobacco, Dr. Galezowski having detailed the results of his experience, as regards the effects produced on the eye (*Annales d'Hygiène*, January), terminated with these conclusions:—(1) Poisoning by tobacco-smoking may, in certain individuals, bring on serious, but curable, visual disturbances. (2) These disturbances only supervene after prolonged and immoderate use of tobacco. (3) In individuals who indulge in the abuse of alcoholic drinks, and in certain idiosyncrasies, tobacco may, even when absorbed in only small quantities, induce such disturbances. (4) For the relief of these affections of the eye, not only must the employment of tobacco be absolutely abandoned, but places where smoking is carried on must be avoided. (5) Remaining for a prolonged time in an atmosphere saturated with tobacco, may prove dangerous for the general health, as well as for the sight; and it is very desirable that effectual ventilation be provided in localities in which smoking is constantly going on, as clubs, cafés, &c.

Therapeutical Eccentricities.—Under this title the *Révue de Thérapeutique*, February 15th, states that Dr. Langenbusch, considering that the gall-bladder is often the receptacle of biliary calculi, that its development varies greatly in different species of animals, that it is absent in the horse and elephant, that its congenital absence in man is by no means absolutely rare, and that at autopsies obliteration of the biliary duct is often met with, arrives at the conclusion that its importance is of very little account in our existence, and accordingly he undertook its removal in a man, 42 years of age, who had suffered from gall-stones since 1866. The operation proved perfectly successful. Professor Vachetta advises in chronic anæmia the injection into the peritonæum of a solution of the citro-ammoniacal albuminate of iron. Excision of a portion of the stomach was performed for the first time in Switzerland by Professor Socin, of Basle, for cancer of the pylorus in a woman 42 years of age. The operation lasted two hours, and, the newspapers say, gives every hope of a successful issue. The success, indeed, is certain as far as the operator is concerned, for he will get himself well talked about; but as regards the patient, the following statistics show the results of sixteen similar operations. Fourteen proved immediately fatal, and in the two others relapse took place in two months. "One is really proud of being a Frenchman when such eccentricities are taking place amongst foreigners!"

Treatment of Albuminuria by Nitro-Glycerine and the Chloride of Gold and Sodium.—*The Boston Medical and Surgical Journal*, January 10th, contains a paper on this subject by Dr. Roberts Bartholow. He considers these remedies of great value. In acute cases nitro-glycerine should be given immediately on the subsidence of the acute symptoms. It is indicated at all periods in chronic cases, but is more especially useful if given before hypertrophy of the muscular layer of the arterioles has taken place. When it acts favourably the amount of albumen in the urine steadily diminishes. The initial dose is one minim of the one per cent. solution, and should be increased until the very characteristic physiological effects are produced; the interval between the doses should not exceed three or four hours. The double chloride of gold and sodium is indicated in the subacute and chronic cases, especially the latter. The earlier it is given the better, if structural changes are to be prevented or arrested. The usual dose is gr. $\frac{1}{30}$ twice a day, but this may be much increased if necessary. At the outset gr. $\frac{1}{10}$ may be given; in a week the dose should be lowered to gr. $\frac{1}{15}$; and, after a month, the regular dose of gr. $\frac{1}{30}$ should be steadily administered with occasional intermissions. It is usually well borne, but if it cause indigestion, gastralgia, and colic pains, nausea, or diarrhœa, the dose must be diminished. The above remedies, if employed together in the same case, should be given uncombined, and at different hours; but the nitro-glycerine may be given with amyl or sodic nitrite; and corrosive sublimate may be combined with chloride of gold and sodium. These remedies may be discontinued if they produce no obviously good effects after two weeks' administration.

Pains in the Side in Phthisis.—These pains (*points de coté*) may precede any other symptom, and then are valuable from a diagnostic point of view; but M. Rigaud, in his thesis on the subject, has chiefly in view their occurrence at later periods of the disease, when they are due to the inflammation caused by the presence of a superficial cavity. There exists a painful condition of all the corresponding region, the pains sometimes becoming very sharp when the thorax is put into motion. M. Rigaud has seen these case

very advantageously treated in M. Legroux's wards by the application of collodion. After washing and drying the part, a succession of layers of this substance is applied to it by means of a badger's-hair brush, until a kind of cuirass is formed, which offers sufficient resistance not to split during the movements of the thorax. If a fissure does occur it must be immediately repaired; and if the pain does not disappear, the procedure must be repeated. In most cases almost immediate relief is obtained.—*Journal de Thérapeutique*, December 2nd.

PROPERTIES OF KAIRIN.—Dr. Crook, of the Post-Graduate Medical School, New York, in a paper published in the *Philadelphia Medical News*, March 22nd, states that the investigations thus far made with regard to kairin justify the following conclusions:—1. It is a decided febrifuge, rapid though somewhat fugacious in its action. 2. It diminishes the frequency of the heart's action to some extent, though the pulse-rate does not fall *pari passu* with the temperature. 3. The symptoms of collapse—cyanosis, cold extremities, &c.—may be entirely or in a large degree avoided by close attention and the proper use of stimulants. 4. It is a tolerably constant diaphoretic. 5. Its action in intermittents, though not fully tested, warrants the belief that it possesses valuable antiperiodic properties, and as such should be carefully investigated. 6. Though it may not be found to possess all the properties of the alkaloid quinia, enough has been learned of its action to justify the hope that a perfect substitute may yet be found, and to inspire us with renewed confidence in the resources of organic chemistry.

IRIDIN IN THE TREATMENT OF THE SICKNESS OF EARLY PREGNANCY.—Dr. Berry Hart recommends the use of two grains of iridin in the form of a pill to be taken at night, and to be followed in the morning by a draught of Friedrichshall water, a teaspoonful of Carlsbad salts, or a doubly strong Seidlitz powder. He states that out of nine cases where this treatment was tried, eight were cured. He was led to the use of this remedy by Dr. Matthews Duncan's allusion to the probable influence of the liver in causing the vomiting of pregnancy.—*Edinburgh Clinical and Pathological Journal*, February 16th.

THE CONDITION OF THE URINE IN SULPHURIC ACID POISONING.—Hoppe Seyler describes (*Zeitschrift für Klinische Medicin*, 1883. Bd. VI., Hft. 5, pp. 478 und 479) the occurrence of an acetone-producing substance in the urine in a case of poisoning with sulphuric acid. The scanty urine, free from albumen, which was passed by a young woman on the sixth day after she had swallowed sulphuric acid, smelt of acetone, and on being tested gave the reactions of acetone. A few days later, when the vomiting and anorexia ceased and she was again able to take nourishment, the acetone disappeared.—*Centralblatt für Klinische Medicin*, January 19th, 1884.

UTILITY OF COCA.—Dr. Hicks, writing in the *New York Medical Journal*, February 23rd, expresses his surprise that this substance is so seldom employed, and enumerates the circumstances under which he has found it highly useful. These are (1) to prevent and relieve fatigue; (2) in backache, accompanied by high-coloured urine, with excess of uric acid and urates; (3) in short breathing from weakness of the muscles of inspiration; (4) palpitation, without valvular lesions, due to dilatation, or weakness of the heart-muscle; (5) it renews the vigour of the intellect, and relieves mental exhaustion, rendering the flow of thought more easy, and the reasoning power more vigorous; (6) it dissipates the "blues," leaving the mind calm; (7) it destroys the craving for alcohol, and in small doses is useful in sick headache, and headache resulting from over-exertion; (8) its habitual use as a part of the daily diet conduces to mental clearness and activity, freedom from fatigue, and sound sleep.

THE TREATMENT OF WHOOPING-COUGH.—In the *Birmingham Medical Review*, for February, Dr. W. H. O. Sankey, lauds a very ancient remedy, viz., carbonate of iron for this disease. He recommends small doses, one grain to each year of the patient up to five or six grains, to be given every three or four hours, and in order to conceal the taste, he suggests that it be administered under the guise of chocolate. He considers that the good results obtained by this treatment afford support to the neurotic theory of the disease, and the well-known beneficial effects of change of air point in the same direction.

NITRITE OF AMYL IN AMMONIACAL URINE.—Professor von Dittel observed at the Vienna Medical Society, that he had for a long time past in obstinate cases of ammoniacal urine found this substance very useful. A solution is made of three drops in 150 of water, and a tablespoonful of this is added to a litre of water, with which the bladder is washed out. The unpleasant smell of the urine diminishes immediately, and is replaced by a pleasant ether odour.—*Allgemeine Wiener Medicinische Zeitung*, January 15th.

A GOOD REMEDY FOR BURNS.—Dr. Finfrock, writing in the *New York Medical Record*, March 22nd, states that, having had during the last twenty years to treat an unusual number of cases of burns, he has found the following remedy by far the best. He first applies powdered bicarbonate of soda, in order to relieve the pain, and then dresses the parts with the following ointment, changing the dressings only when the discharge renders it absolutely necessary: ℞ Ceræ Flavæ ʒj, Ol. Lini Rectif. ʒiii, Acid. Tannic. ʒj, Bismuth. gr. xx. Melt the wax in a clean tin or porcelain vessel, add the oil, and heat to nearly boiling. Remove from the fire, and add first the tannic acid finely powdered, and then the bismuth. To be thoroughly incorporated by stirring until cold.

THE TREATMENT OF DIPHTHERIA BY PAPAYOTIN.—During the last few years Dr. Schöffer has tried most of the remedies recommended to be used in cases of diphtheria, and obtained the best results from papayotin; last summer he treated 47 cases with a five per cent. solution (of papayotin). He begins the treatment as soon as possible, and orders the patches to be painted every five or ten minutes with this solution; in a few hours the membranes are said to be removed, and at the same time the fever disappears. Ewald suggests that an active pancreatic extract should be used instead of papayotin.—*Berliner Klinische Wochenschrift.*

FORMULA FOR HÆMORRHOIDS.—Dr. B. Lee, of Philadelphia, recommends the following: ℞ Pulv. Rhei ʒiv; Pulv. Aloes ʒiii; Pulv. Myrrhæ ʒii; Sapon. Hispan. ad ʒii Ol. Cajeput ʒi. The powders are to be rubbed up together, the soap worked in, and then the oil. The well-mixed mass should be used as fresh as possible, and should be kept in air-tight bottles. Three grains of the mass make an effective pill, which is not irritating, and may be used a long while without diminishing the susceptibility of the intestines, and often with positive benefit to the hæmorrhoidal affection.—*New York Medical Record*, February 9th.

INUNCTION OF QUININE.—The *Louisville Medical News*, March 29th, quotes the highly favourable opinion entertained by Dr. Wale, of Missouri, of the great efficacy of quinine mixed in lard as a means of treatment of intermittent fever or other malarial disease in infants. Of 162 infants under twelve months, treated for intermittent and remittent, since 1830, he has only met with three failures—the amount employed being about three times that required when given by the mouth. This is mixed with a teaspoonful of lard, divided into three parts, and rubbed on to inner side of the thighs and groin, one part every two or three hours. To be effectual, the rubbing-in must be completed several hours before the expected paroxysm. If the paroxysm is not lessened, the rubbing should be repeated next day, and if lessened the amount used should be in proportion less. In only a minority of cases has a repetition beeen required, but occasionally two repetitions have been called for. For young infants many physicians give too small doses, a young infant requiring a larger dose than an older one.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON,

TUESDAY, APRIL 15TH, 1884.

J. WHITAKER HULKE, F.R.S., President, in the Chair.

Cirrhosis of Liver.

DR. F. C. TURNER showed a specimen of well-marked cirrhosis of the liver, the microscopical appearances were characteristic, the overgrowth of connective tissue being considerable, the liver cells were much degenerated, and there was a good deal of fatty change in places. Groups of dilated biliary ducts surrounded the margin of the tracts of fibrous tissue. A blood clot occupied several branches of the portal vein; mingled with the corpuscles were fragments of liver cells, and of the epithelial lining of the ducts. Laceration of liver tissue could be seen at one place where there was a similar commingling of blood and liver substance as in the portal veins. This laceration must have taken place shortly before death. No liver cells were found in the hepatic venules, probably because they would have been carried to the heart. There was some analogy to the fat embolism seen in cases of fracture of long bones when the medullary canal was damaged. The specimen was noteworthy also in connection with biliary cirrhosis. But the cirrhotic tissue in this case did not originate in an irritative lesion of the bile ducts, because the ducts in this specimen fringed the tract of connective tissue, their increased development was secondary rather than primary. There was no direct continuity between the epithelium of the ducts and the liver cells as maintained by Sabourin, Woodhead, and others. The progressive growth of bile ducts might be due to atrophy of the liver cells. He had no history of the case, but assumed that the liver had been enlarged and corresponded with the condition usually described as biliary cirrhosis.

Dr. CARRINGTON asked whether the appearances could not have been due to the preparation of the section, and what other evidence there was of destruction of the liver.

Dr. GOODHART said this case raised the question as to the nature of biliary cirrhosis. The question was a very difficult one, statements were made and accepted without question, many did not believe in its existence.

Dr. TURNER could not agree that the liver cells could have got into the portal vein by accident. He could not suggest any other explanation than the one he had already given.

Abscess of the Brain.

Dr. CAYLEY said the specimen was taken from the body of a man, aged 18. He had suffered from pleurisy and hæmoptysis. Headache and loss of power on the left side were the earliest symptoms. There was no loss of sensation and no mental impairment. Signs of disease of left lung were found. On the day after admission he had a left-sided convulsion, without loss of consciousness, commencing in the leg. After this the pupils were unequal. There were no ophthalmoscopic changes. The temperature was decidedly subnormal. A few days later death took place. An abscess was found in the right centrum ovale, with a distinct lining membrane, destroying the upper part of the ascending parietal convolution. On the left side there was an abscess in the temporo-sphenoidal lobe. There was old disease of the left lung. During life the case had been regarded as one of tubercular tumour. Had the abscess been suspected, trephining would have been easy, and probably successful.

The PRESIDENT had been interested in the continuous low temperature, he had seen the same thing also in cases of traumatic abscess of the brain.

Dr. EWART noted that both abscesses were in the course of the distribution of the middle cerebral artery. It suggested that they were due to conveyance of pus from the diseased lung.

Primary Cancer of the Liver.

Dr. W. TIVY read notes of this case. The patient was a woman, aged 51, whose illness dated from June, 1883, when she suffered from dyspeptic symptoms and enlarged abdomen. She had noticed a small lump in right side of abdomen since 1861. There wa s a family history of phthisis, and an aunt and cousin had had cancer. There was no suspicion of syphilis, and her general health had been good. She was subject to psoriasis. There was a large and hard nodulated tumour in the right hypochondrium, no ascites, and no signs of disease elsewhere. The abdomen rather rapidly increased in size. In November, having had slight mental symptoms for a few days, she had a series of epileptic convulsions, and remained unconscious till her death, a few days later. At the necropsy there was a large cancerous tumour of the liver, but the other viscera were healthy. The liver weighed 9 lbs., the right lobe was infiltrated throughout, and the left lobe contained numerous tumours, some portions of them being somewhat hard. Microscopically, in places there was very little fibrous tissue and many cells, but in other places there was a large amount of fibrous tissue. He assumed there had been a scirrhous tumour at first, which had taken on an encephaloid type. There were many points of clinical interest, especially the long duration of the disease, the non-affection of other viscera, and the absence of jaundice and ascites.

Cerebro-spinal Meningitis.

Dr. CARRINGTON said that the first patient was a Swedish seaman, aged 27. He had ailed two weeks, restlessness, insomnia, and headache were the chief symptoms. His neck was rigid, and head a little retracted. Marks of syphilitic eruption were found on the thighs and legs. A few days later, petechiæ appeared on the trunk, and herpes on the lips. The deep and superficial reflexes two days later were absent. Next day there was optic neuritis, and four days later he died. At the *post-mortem* there was a good deal of lymph on the under surface of the pons, and in the neighbourhood of this, some lymph extended down the front of the spinal cord, but not at the upper part. The internal ears were healthy. The second patient was also a Swede, aged 20, he had similar symptoms, but no history could be obtained. He also had some rigidity of the neck. There was not much eruption; there was some facial paralysis a few days before death. At the autopsy, the convolutions were flattened, and the arachnoid was sticky, the sub-arachnoid space was dilated, and the parts around third ventricle were softened, a little lymph for about two inches down the cord. Other organs healthy, internal ears healthy. He had been unable to trace either of these patients on leaving their ships. He noted that there was a large amount of pus in the first case, but very little in the second.

Mr. JESSETT mentioned an outbreak he had seen amongst some troops, and referred to a theory that the disease broke out in ships which had been used for conveying cattle.

Dr. TURNER said that two cases had been admitted into the London Hospital on March 6th and March 16th. The

first was a black sailor, who died three days after admission; he was delirious all the time, his neck was stiff, and the left leg was weak. There was purulent lymph over brain and down posterior aspect of spinal cord in each case, but not at the base of the brain. The symptoms of the second case, he believed, were similar.

Mr. Ernest Clarke mentioned the case of an infant he had seen at Lewisham about the same time, in which death occurred on the third day, there was general purulent meningitis.

Congenital Tumour of the Back.

Mr. Davies-Colley had removed this from a boy, aged 16; it had grown ever since birth, more rapidly of late. A month before he came it had begun to ulcerate. It was flat, extending from the fourth to the tenth dorsal spines, the pedicle was very short, the tumour was four inches in breadth, it was freely movable, and the skin was movable over it, the ulcer was an inch in diameter. It was of uniform firmness, lobulated, of granular feel. It was removed, and recovery was rapid. There were loculi of various sizes with thin fibrous partitions, out of them small glandular-looking bodies dropped out like enlarged lymphatic glands. The nodules had a delicate stroma with many fusiform cells, their nuclei being elongated. It was a fibro-sarcoma; but originally was polycystic, and subsequently there had been a development of fibro-sarcomatous growth. It reminded him of fibro-cystic disease of the breast. No cartilage or bone was present.

Mr. Butlin thought that Mr. Davies-Colley's case opened several points for pathological discussion. If the tumour was cystic and congenital, it was not improbably, in the first instance, a cavernous lymphatic tumour, and it was very unusual for intra-cystic growths to be developed in the interior of the cystic cavities of such tumours. The origin of the intra-cystic growths was also a matter of doubt; it seemed more likely that they grew from the material which lay between the cysts than from the endothelium which, presumably, lined the cysts. Although the structure of the tumour led to the use of the term fibro-sarcoma, he could hardly believe that the fusiform cell tissue, which appeared to be tolerably abundant, had the same signification as in a true sarcoma, for he thought it improbable that the disease would prove to be in any respect malignant.

Enchondroma of Lung.

Dr. Norman Dalton exhibited some microscopical preparations from a case of this disease. He said that the mediastinal glands were enlarged forming a hard mass. In the right lung just above its root was a tumour which towards the mediastinum was hard and white, whilst towards the lung it was softer and yellowish. The tumour was found to consist of hyaline cartilage apparently in the walls of the air-cells, the cavities of the air-cells were occupied by masses of large cells like embryonic cartilage. The mediastinal tumour showed a similar structure. There were thrombi in the veins of the right side of the neck, almost completely decolourised.

Card Specimens.

Dr. F. C. Turner. (1) Duodenal ulcer, fatal hæmorrhage, pouching of the duodenum. (2) A similar specimen. (3) Ulceration of the pylorus. (4) Spinal cord from a case of cerebro-spinal meningitis.

Mr. Lane. (1) Fracture of the hyoid bone, with deformity of the thyroid and cricoid cartilages. (2) Fracture of the seventh and eighth costal cartilages. (3) Diphtheria of larynx spreading upwards to pharynx.

Dr. Carrington. Cancer of gall bladder.

Dr. Barnes. Calculus vesicæ.

Mr. Sutton. (1) Dissection of stump. (2) Separation of epiphysis of fibula.

Dr. Hale White. Hour glass constriction of stomach.

HARVEIAN SOCIETY OF LONDON.

Thursday, April 3rd, 1884.

George P. Field, M.R.C.S., President, in the Chair.

Discussion on Scarlet Fever.

In his opening remarks, Mr. Cripps Lawrence gave out the following heads for discussion:—(1) Ætiology of Scarlet Fever; (2) Surgical Scarlet Fever; (3) Puerperal Scarlet Fever; (4) Differential Diagnosis.—(1) *Ætiology.* The virus of scarlet fever is undoubtedly specific, but while most believe it to be an organised body, as yet its existence has not been demonstrated. The specific action of the virus is manifested in the uniformity which scarlatinous blood exhibits microscopically; by the reproduction of the disease when such blood is injected into healthy animals, or inoculated into the human subject; and by the power of propagation possessed by the inoculated form. While holding the view that desquamating cuticle is one of the chief means by which scarlet fever is transmitted, Mr. Lawrence noted that this belief was not universal in the profession, and that a German authority had denied that the epidermal scales were infectious. The possibility that eczema, urticaria, pityriasis, measles, and rötheln, may be associated with desquamation, and possibly sore throat, renders it imperative to avoid precipitancy in diagnosis as well as dogmatic assertions which may injure a professional brother. The chief characteristics of the scarlatinal poison were briefly referred to, such as its volatility, its durability, and its transmissibility by unaffected persons. The speaker also dealt with Suppressed Scarlet Fever and with Recurrent Scarlet Fever. (2) *Surgical Scarlet Fever* was not a new disease. Mr. Germain Sée noticed, in 1858, following upon tracheotomy, an eruption closely allied to scarlet fever. From theses by M. Trélat and Mr. E. C. Stirling the following propositions could be gathered:—(*a*) Scarlet fever may be an immediate sequel of operations; (*b*) it exhibits certain variations; (*c*) it more or less retards cicatrisation of the wound; (*d*) a wound is a necessary condition for its production; (*e*) various eruptions, other than scarlet fever, may follow operations, wounds, and injuries. The views of Sir James Paget, of Mr. Howse, and Dr. Goodhart were quoted. Some doubt was expressed as to the possibility of a latent scarlet fever, and of an indefinite incubation. (3) *Puerperal Scarlet Fever* was a variety, having an incubation period of from twenty-four to forty-eight hours. Mr. Lawrence referred to five labours associated with puerperal scarlet fever: one mother escaped, although malignant scarlet fever deprived her of four children during the week of her labour; four mothers recovered after severe scarlet fever; one infant died, two infants escaped, and two recovered. The address by Dr. Priestley, at the Obstetrical Society in 1876, gave the results of a discussion on this topic. Mr. Lawrence noted the marked frequency of pulse which followed the third stage of labour, as an initial symptom in the cases of puerperal scarlet fever observed by him; and he enquired whether rupture of the perinæum was a constant factor in such cases. (4) The *Differential Diagnosis* was considered with reference to measles, roseola, and rötheln, in connection with incubation, eruption, temperature, and state of the tongue, cervical glands, and throat.

Dr. Broadbent concurred in the view that the disease depended upon some organic contagion. Among the ætiological moments were mentioned the varying liabilities of families, of social classes and of race. In France the name of scarlet fever inspired no terror, the disease being regarded by the public and by the profession as relatively devoid of danger. In many families an inverse relation had been observed to exist between the liability to scarlet fever and the liability to measles. With reference to surgical scarlet fever occurring in cases where no definite exposure to the poison could be traced, Dr. Broadbent suggested that the depression of vitality consequent upon wounds might produce a susceptibility for diluted doses which in health exercised no evil influence. A case was mentioned, which occurred after tracheotomy, and led to the nurse being subsequently affected. Reference was also made to suppressed

scarlet fever, and to cases in which a form of puerperal fever was the outcome of the scarlatinal poison; the appearance of genuine symptoms of scarlet fever under similar circumstances was a comparatively hopeful indication.

Dr. MAHOMED dwelt upon the fact that scarlatina was not always propagated by contact with infectious persons. He remarked upon its occasionally endemic character, and quoted cases in which it had repeatedly occurred in houses associated with other cases of septic poisoning, and was clearly traceable to sanitary defects. He thought it not infrequently a "drain disease." Although he did not believe in its spontaneous generation, yet he thought it very probable that a comparatively innocent germ or ferment could take a more malignant character; in fact, he believed in the evolution of the poison. He referred to the recent observations on the jequirity fermentation as throwing light on the relation of bacteria to disease, of which he thought we knew but little; he thought it quite as probable that the disease caused the bacteria, as that the bacteria caused the disease. He strongly affirmed the risk arising from desquamation, which he stated could not be prevented, though it might be diminished by the use of antiseptic inunctions. He had seen the infection retained and transmitted for the longest periods by slight cases in which the desquamation was fine and powdery; he had known such a case convey infection eleven weeks after the commencement of the illness. With regard to surgical scarlet fever, he regarded it as the same disease as ordinary scarlet fever, he had seen such cases transmit the ordinary disease to others. He stated that the disease in this form was generally mild, and that it ran an abbreviated course in its incubation, fever, sequelæ, and desquamation. The albuminuria occurred much earlier in such cases than in the ordinary disease. He believed that scarlatinal poison was highly dangerous to puerperal women. Its most common effect upon them was to produce a more or less malignant form of septicæmia. He regarded those cases as fortunate which, having been exposed to scarlatinal poison during the puerperal state, developed recognisable scarlet fever. Although it was possible for such cases to have the disease mildly, he believed that it was more commonly severe; he had made *post-mortem* examinations of two such, in which typical puerperal peritonitis was associated with true scarlatina. Concerning diagnosis, Dr. Mahomed held that we must be most lenient in judging of the mistakes of others. Some cases it was impossible to diagnose correctly. He had known cases with normal temperatures on the second day. He wished to know the experience of members concerning the indications afforded by convulsions during the early stages of the disease. In his experience they were almost invariably fatal. With regard to the diagnosis of rubeola, he disagreed with Mr. Cripps Lawrence as to the duration of the premonitory symptoms; he had seen the characteristic enlargement of the glands three or four days before the appearance of the rash. He did not think that rubeola ever desquamated profusely, and had preferred to change his diagnosis when cases thought to be rubeola had so desquamated. He had placed two such cases in the scarlatinal ward without their contracting the latter disease.

Mr. PEPPER, after reviewing the evidence in favour of the disease being due to the agency of micro-organisms, pointed out that it was reasonable to expect that an open wound might admit the infection, and that in such a case the symptoms would develop more rapidly by reason of the direct absorption of the poison. In some instances the period of incubation of surgical scarlet fever had not exceeded twenty-four hours. In his own experience, at the Fever Hospital, cases of surgical scarlet fever had generally done well.

Mr. W. B. OWEN drew attention to the existence of a mode of transmission hitherto overlooked but calling for serious vigilance. In a charity school six children, who sickened simultaneously with the disease, were found to have had access to a bunch of flowers, which was subsequently traced back to a house infected with scarlet fever.

Upon a motion by Mr. PEPPER, seconded by Dr. ALDERSON, the discussion was adjourned to May 15th.

THE TERCENTENARY FESTIVAL OF THE UNIVERSITY OF EDINBURGH.

DURING the present week there is being celebrated in Edinburgh an event which cannot fail to be of interest to every Briton, as well as to all those throughout the world who have at heart the propagation of knowledge, science, and general culture. The capital of the north has witnessed many pageants in its time. It has been the seat of war, siege, and revolution. It has welcomed kings, and sheltered them in their need. It has had its military glories and defeats. It has never, however, had occasion for a celebration of which it has more reason to be proud, than that which it now holds in rejoicing over the completion of its third century of academic usefulness, and commemorating the three hundredth birthday of its University. This great national institution has from its earliest foundation been actuated with the earnest belief in the beneficial effects of widespread human knowledge. It has regarded education as the first requisite for the good of society, it has sought to extend information in all directions, and there is no region of the earth that has not been fructified by its labours. Wherever Scotsmen are—and to what parts of the world do they not penetrate—there some of the good that the Edinburgh University has done will be found, and through them its beneficial influence has been universally disseminated to the advantage of humanity. It has sent culture, and healing, and scientific skill broadcast throughout the nations, and has everywhere made the name of Scotsman synonymous with energy, and knowledge, and power. If Edinburgh cannot boast of wealth, commercial enterprise, and the acquisition of those elements which characterise other large cities of this great empire, it nevertheless contributes richly to the well-being of the nation, and to the successful progress of mankind. A distinguished politician recently demanded of one of its inhabitants, "What is the chief industry of your town?" The reply was, "Our chief industry is education." This, in the absence of the mere acquisition of gain, is the boast and pride of our northern capital, and it is this noble object which has ever animated its efforts, and has attracted learned men from all quarters of the globe to offer their congratulations on the completion of the tercentenary of its University.

Although Edinburgh is the youngest of the four great educational centres which elevate and dignify Scotland, it is more completely than any of them, the production of the national spirit and genius. It is as impossible, as it is unnecessary, for us to enumerate the long roll of eminent and illustrious names which have adorned its history, or the triumphs of discovery and science which have been disseminated through its influence. The list is so long and so brilliant as to be a part of history, and is familiar to all those to whom education and culture are a source of attraction. A proof of the estimation in which the University is held by the world of learning, is now being demonstrated by the gathering which is at present taking place to do it honour. Every quarter of the civilised globe is sending representatives to testify to the respect and admiration in which it is universally held. At its festival is assembling such a phalanx of intellect and distinction as has not been superseded in past history. The most eminent and celebrated delegates are announced from all the British, foreign and colonial learned bodies. No less than seventy-two Universities are to be thus represented, and the countries outside the United Kingdom in which these are situated are France, Germany, Holland, Belgium, Norway, Sweden, Switzerland, Italy, Denmark, Portugal, Russia, Austria, Hungary, Bohemia, Poland, India, America, Canada, New Brunswick, Australia, Brazil, Chili, and the Cape of Good Hope. Besides these, there are representatives from all the leading educational and public bodies, and the literary and scientific societies of Europe. In addition, hundreds of distinguished guests are being entertained by the city, and gracing the academic ceremonial proceedings by their presence. Finally, there have gathered together from all parts of the kingdom multitudes of the alumni and students of their *alma mater*, to demonstrate the gratitude and love which they

entertain for all the benefits they have received at her hands.

This vast concourse of those interested in the pursuit of knowledge are devoting this work to a jubilee on the anniversary of their University's birth. Every day is occupied with ceremonials in its honour, and entertainments which are provided by the authorities and citizens of the town, to their guests, in commemoration of the festival. Occasion is taken to confer on a large number of distinguished theologians, and men of science and letters of all countries, honorary degrees, of which upwards of one hundred and twenty will be conferred with great ceremony, in recognition of their devotion to and success in intellectual pursuits. *Conversaziones*, receptions, and amusements of all kinds are without number, and the public bodies and private citizens of the town vie with one another in dispensing an abundant and welcome hospitality.

Although the University of Edinburgh recognises and promotes all departments of knowledge, there can be little doubt that it has been chiefly pre-eminent in the cultivation of medical science; and the long *rôle* of illustrious teachers, and the beneficial influence these have exercised on this branch of learning, has been admitted by all, and felt throughout the world. The general appreciation of this fact is illustrated by the distinguished list of our own profession who have felt honoured in receiving the complimentary degrees which have been offered them on the present occasion. Amongst those who are to receive the diploma of LL.D., we observe the names of Jenner, Gull, Paget, Bristowe, Clark, Erichsen, Balfour, Barker, Bowman, Keith, Maudsley, Marshall, Sieveking, Acland, Carus, Virchow, Helmholtz, Donders, and Pasteur.

At no period during the history of the University has its influence borne more luxuriant fruit than at the present time, and the fame of its former reputation and genius has attracted to its school unprecedented numbers of pupils. Of late years there have been nearly two thousand students pursuing a medical curriculum within its walls, thus constituting it the largest medical school in the kingdom, and the new hospital and college may rank as the most perfect and complete of their kind in the world. Long may this success in the promotion of our noble science continue to flourish, and be the admiration of all who have at heart the cultivation of its principles. We add our congratulations to those which are justly being accorded during the present week to our great national University, and we earnestly trust that it will long continue to be an enduring source of enlightenment, the promoter of knowledge, the cultivator of genius, the help of the struggling, and the pride of all men who seek to make the world better than it is.

GENERAL CORRESPONDENCE.

THE PSYCHICAL RESEARCH SOCIETY AND "CLAIRVOYANCE."

[To the Editor of the Medical Times.]

SIR,—Dr. Donkin has brought a charge of "untrustworthiness" against the tests adopted by a committee of the Society for Psychical Research in a recent enquiry. It must surely be rash to describe any method or test as untrustworthy *per se*, and without reference to some particular results and conclusions. Thus, suppose the subject of experiment to be the sensibility of the retina after hypnotisation; suppose that the test adopted is to hold up cards at a distance, and to ask the hypnotised person to name them; and suppose that twenty cards in succession are correctly named. It would then be legitimate to conclude that the retina must have *retained* its sensibility; and with reference to that conclusion the test would be trustworthy. But now suppose that under the same conditions the hypnotised person fails to name the cards. It would not, then, be legitimate to conclude that the retina must have *lost* its sensibility; for there are other possible reasons (*e.g.*, mental torpor, or a wish to mislead) which would equally account for the failure; so that with reference to that conclusion the test would *not* be trustworthy. This example sufficiently shows that the trustworthiness of a test is not an independent quality, but must have reference to some conclusion to which the application of the test has led. Now the conclusion to which the committee has been led in the present instance cannot possibly be known to Dr. Donkin.

But Dr. Donkin's rashness has gone further than this. His representation is, that in these experiments, which were on a case of alleged clairvoyance, untrustworthy tests in the way of blindfolding were applied by the committee, and that then the power of vision remained; but that an expert, being introduced, applied trustworthy tests, and that after that the power of vision ceased. It follows that by trustworthy tests Dr. Donkin means, in this instance, tests which effectually bar all power of vision. It is unfortunate, therefore, that the particular tests which he commends as trustworthy by no means fulfilled that condition. For on subsequent occasions, not only these, but decidedly more stringent and complete methods of blindfolding were adopted—methods involving all the points of Dr. Donkin's trustworthy tests, and several others besides—and vision turned out to be still perfectly possible. But, what is more—vision turned out to be possible not only to the alleged clairvoyant, but to a member of the committee, whose eyes were plastered up and bandaged in the precise manner which it seems that Dr. Donkin would have hastily concluded to be efficacious. And—yet one further surprise—the particular additions to which Dr. Donkin attaches such virtue, the old expedients of a pad of cotton-wool and a penny fixed over each eye, so far from barring vision were found actually to facilitate it; for while they afford no security against the presence of minute crevices, the additional darkness and the pressure on the eyeballs seem to give a double chance to the faint rays of light which the crevices admit. Information of this kind can only be obtained by our plan of testing the efficacy of blindfolding from *inside* instead of from *outside*; and this was the essential feature of the method of enquiry which Dr. Donkin so contemns. Not, of course, that the standard of efficacy thus obtained is absolute. A practised person might succeed in performing feats with his eyes which could not be imitated by an amateur; and this supposition seems specially applicable to the case of a hypnotised "subject," inasmuch as he naturally keeps his eyes in a position which is favourable to seeing upwards through crevices, and which is a most strained and fatiguing one to a person in a normal state. But though not exhaustive, the method was, at any rate, amply sufficient to show that the tests represented by Dr. Donkin as trustworthy were thoroughly untrustworthy; for they failed to block even quite unpractised powers of vision.

From such tactics as Dr. Donkin has here pursued, those whom he attacks have everything to gain. The only person likely to complain is the "expert," whose description of a fragment of our proceedings seems (I am sure without his intention) to have inspired the attack. For through no fault of his own, the request which he has courteously renewed, to be allowed to assist at some more of our experimental work, has been made by his friend's indiseretion extremely difficult to grant. Is there a laboratory in England where the chance would be given a second time for a course of experiments to be attacked before its results have been recorded, on the strength of a casual description of one of its inchoate stages?

I am, Sir, yours, &c.,

April 13th, 1884. EDMUND GURNEY.

THE MERCHANT SHIPPING BILL.

[To the Editor of the Medical Times.]

SIR,—Having recently (*Land and Water*, March 22nd) written at length on the Merchant Shipping Bill, in this paper I need only give very briefly a few of the more glaring conspicuous errors of omission and commission of the Bill now before Parliament. For obvious reasons I shall deal principally with the "living machinery," to which little or no attention has been paid by the President of the Board of Trade.

1. Scurvy, which seems to be a veritable *bête noir* to the officials at Whitehall, is not even mentioned; from this one might naturally infer that the disease is no longer met with. Such, however, is not the case, as may be gathered from the last report of the Seamen's Hospital Society, in which it is stated that the number of cases admitted during the year 1882, though lower than those of the ten preceding years, contrasts very unfavourably with the returns of 1873; and in an official report issued by the Marine Department of the Board of Trade, it is shown that the average number of scurvy outbreaks reported since 1875 has been 86, whilst in 1869 and 1870 only 22 cases had been recorded. Notwithstanding the increased prevalence of the disease, I learn with regret that "it is not at present considered desirable to insert a statutory scale of diet in the articles of agreement with crews serving on long voyages, though it may possibly be necessary at some future period." Such "masterly inactivity" on the part of the Marine Department of the Board of Trade, in thus compelling year after year our merchant seamen "to stew in their own juice," cannot be considered very commendable, the more especially when it is remembered that an obligatory dietary scale, as I have so repeatedly pointed out in the *Times*, would be the means of completely "stamping out" the disease. On this point all authorities are agreed.

2. The inspection of provisions is the second point to which I would draw attention. The emigration officers are *supposed* to inspect the provisions on board vessels taken up to convey emigrants, but only the stores for the use of emigrants, and not those for the crews. Re-shipment of provisions should be prohibited; a stop should also be put to the plan of provisioning first-class merchantmen going long ocean voyages with the surplus stores of the steamship companies. It is not at all uncommon for stores to be taken twice to the Antipodes before being consumed; they are thus subject to constant change of climate, &c., which it is obvious cannot improve them. Tinned provisions, so universal on shore, would be a wholesome change for the salt beef and salt pork, varied only by salt pork and salt beef. One word with regard to alcoholic beverages. "Jack" likes his glass of grog, and at certain times, *e.g.*, when exposed to wind and rain, hour after hour, it should not be withheld. Total abstinence on board ship has, I think, been pushed a little too far. That wine "gladdeneth the heart of man" is approved on the highest authority, and that it is a true food was stated by Dr. Druitt, and proved beyond "the shade of a shadow of a doubt" by Dr. Parkes in his experiments at Netley.

3. The total abolition of all permissive clauses relating to the inspection of seamen, in order to ensure efficient manning and safety of vessels.

4. An extension of the Contagious Diseases Acts to the waterside parishes of the chief mercantile ports.

5. The appointment of legally qualified medical men on every ship bound to carry a surgeon. As this is a subject to which you have very recently drawn attention, I need not further expatiate upon it.

Such are a few of the short-comings of the Merchant Shipping Bill, of which the Marine Department of the Board of Trade does not appear to be cognisant, and, although I have for years past persistently drawn attention to the subject, believing with George Eliot, "That it is not only laying hold of a rope, we must go on pulling," I would remind these officials that—

> "Omission to do what is necessary
> Seals a commission to a blank of danger;
> And danger, like an ague, subtly taints
> E'en when we sit idly in the sun."

I am, Sir, yours, &c.,

W. DOMETT STONE.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

[To the Editor of the Medical Times.]

SIR,—I shall be obliged if you will kindly permit me to make known through your columns that an Association is being formed for the purpose of promoting the interests of Members of the Royal College of Surgeons of England. The whole government of the College is in the hands of the 1,100 Fellows, the 16,000 Members being absolutely precluded from expressing their views except through the medium of the public press. Speaking generally, the objects of the Association will be to obtain a voice in the management of the College, by securing a General Meeting of the Fellows and Members of the College every six months; to promote the dignity and value of Membership of the Royal College of Surgeons of England; and to concern itself with the welfare of members and of the profession at large. I shall be glad to receive the names of any members who may be willing to co-operate.

I am, Sir, yours, &c.,

JAMES ROCHEID FORREST.

59, *Lowden Road, Herne Hill, London, S.E.*
April 16th, 1884.

MEDICAL NEWS.

RUSSIAN MEDICAL LITERATURE.

DR. MAX BACH, writing in the *Deutsche Medicinische Wochenschrift*, of the 28th February, observes, that it is scarcely known in Germany, that a noteworthy Russian medical literature exists. Only a few journals have of late years began to report on Russian works, and in the great medical retrospects, such as Hirsch and Virchow's Jahresberichte, we may look in vain for any account of a Russian medical work, or with few exceptions, any reviews of the Dorpat dissertations, although these are written in German, are accessible in the University libraries, and are declared by Hyrtl to be classical productions, as regards minute anatomy. On the other hand, every small production in Swedish, Danish, or Polish medical literature is carefully registered, and reported upon. The natural conclusion would be that Russian medical literature is so insignificant, that the Germans incur little loss by not being furnished with any notice of it. But this is far from being the case. The Russian monthly journal, *Medicinische Rundschau*, gives a list of the journal articles which appeared during 1882, and the first half of 1883, but unfortunately this does not include the transactions of medical societies, several of which are published periodically, and contain numerous excellent articles. According to this statement, Russia possesses seventeen medical journals, a few of which are confined to special subjects, such as psychiatry, and neurology, medical jurisprudence, military hygiene, &c. In 1882, they contained contributions from 477 writers, and in the first half of 1883, there were 292 authors. If we add to these the transactions of several medical societies, and numerous excellent theses, besides independent works and brochures, we may certainly assume that nearly a thousand independent medical productions are annually printed in Russia. Admitting that many of these publications are taken from French or German journals, and that others are of but little value, yet there are hundreds of communications of importance, of which neither Germany, nor the medical world at large, knows anything whatever. This omission is so complete, that the Russian translators of English, French, or German manuals, are compelled to add long appendices, in order to include the Russian contributions.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Board of the Examiners on the 10th instant, and when eligible will be admitted to the pass examination, viz:—Messrs. W. H. R. Rivers, H. J. Fylden, C. J. Davenport, W. H. Hamer, H. C. O. Schofield, and B. W. Quartley-Papaflo, of St. Bartholomew's Hospital; J. J. Clarke, of St. Mary's Hospital; G. C. W. Wright, H. M. Doyle, C. F. Wright, and William Parker, of London Hospital; William Goos, W. J. Colborne, and Edward Edwardes, of Charing Cross Hospital; W. A. Furmstone, H. L. Williams, and W. R. Clay, of Middlesex Hospital; J. F. Calvert, and H. P. Helsham, of St. Thomas's Hospital; and H. W.

Drew, of Guy's Hospital. Four candidates having failed to acquit themselves to the satisfaction of the Board of Examiners were referred to their studies for three months. Passed on the 15th instant:—Messrs. F. W. Green and G. L. Turnbull, of St. Bartholomew's Hospital; J. T. Thomas and L. A. Bidwell, of St. Thomas' Hospital; A. J. Gedge, A. E. Richardson, J. Godding, C. F. Fenten, and A. B. Roxburgh, of London Hospital; A. Buckell, S. E. Holder, C. W. Jeeks, and S. P. Hosegood, of University College Hospital; H. R. Davies, L. Remfry, and G. de V. Belson, of St. George's Hospital; C. F. Routh Fisher, of Guy's Hospital; W. R. Ackland, of Charing Cross Hospital; W. H. B. Moore, of King's College Hospital; and H. B. Brackenbury, of Westminster Hospital. Three candidates were referred for three months. The following candidates passed their primary examination on the 16th instant:—J. H. Tonking, C. T. Quiller, E. C. Stabb, H. J. Smyth, of St. Thomas's Hospital; A. C. Richards, H. J. Hawthorn, H. G. Lys, L. C. E. Calthrop, of London Hospital; F. H. Andrews, of St. Bartholomew's Hospital; J. O. Tunstall, F. S. Toogood, of University College Hospital; T. W. Gibbard, G. C. Jones, A. E. Hensley, of King's College Hospital; H. S. Cooper, of Westminster Hospital; C. W. Hogarth, H. V. Rake, of Guy's Hospital; and H. E. Mann, of St. George's Hospital. Six candidates were referred for three months. The following condidates passed their primary examination on the 17th instant:—S. A. Tidey, of St. Mary's Hospital; J. S. W. Chitty, of Charing Cross Hospital; C. C. Burt, of Westminster Hospital; F. F. Burghard and G. Black, of Guy's Hospital; A. W. Pearse and S. B. Cook, of St. Thomas's Hospital; A. J. Macnab and R. J. Stephens, of King's College Hospital; P. J. De Nyssen, of St. George's Hospital; N. R. Howse and W. D. Calvert, of London Hospital; and W. P. May and A. J. Lang, of University College Hospital. Two candidates were referred for three months, and one for six months. 256 candidates presented themselves for the examination just completed, as compared with 222 at the corresponding period of last year; of this number 45 were referred to their anatomical and physiological studies for three months, and three for six months, making a total of 48 referred candidates.

Royal College of Surgeons.—It is stated that nearly 250 candidates have just entered in their names for the final examination for the diploma of membership of this institution.

The Library of the Royal College of Surgeons.—This library will be closed to day (Friday, April 18th) for the purposes of the examinations.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, April 10, 1884:—

McCarthy, Philip Augustine, Victoria Road, Battersea Park.
Russell, Robert Hamilton, King's College Hospital.
Vernon, Fredk. Wm., Manor House, Poplar.

King and Queen's College of Physicians in Ireland.—At the monthly examinations for the licences of the College, held on Monday, Tuesday, Wednesday, and Thursday, March 10th, 11th, 12th, and 13th, 1884, the following candidates were successful:—For the *Licence to Practise Medicine*—Henry Bullen Beatty, Dublin; John Craig, Dublin; Godfrey Oldfield Cuppaidge, Kingstown, Dublin; Robert Hickson, Kingstown, Dublin; Benjamin Rigby Johnston, Ambleside, Westmoreland; Christopher Peter Kelly, Navan, Co. Meath; Margaret Morier, Aberdeen, N.B.; Henry Ross Todd, Dublin; George Robert Williams, Larne, Co. Antrim; Samuel Richard Wills, Rathkeale, Co. Limerick. For the *Licence to Practise Midwifery*—Henry Bullen Beatty, Dublin; Godfrey Oldfield Cuppaidge, Kingstown, Dublin; Robert Henry, M.D., R.M.I., Donaghadee; Robert Hickson, Kingstown, Dublin; Benjamin Rigby Johnston, Ambleside; Margaret Morier, Aberdeen, N.B.; Patrick Neary, Ardee, Co. Louth; George Bobert William, Larne, Co. Antrim; Samuel Richard Wills, Rathkeale, Co. Limerick. The undermentioned Licentiates in Medicine of the College, having complied with the by-laws relating to membership pursuant to the Supplemental Charter of December 12th, 1878, were duly enrolled members—John Christal, *Lic. Med.* 1876, Cootehill, Co. Cavan; Charles Scovell Grant, *Lic. Med.* 1877, Gold Coast Colony, West Africa.

At the monthly examinations for the Licences of the College, held on Monday, Tuesday, Wednesday and Thursday, April 7th, 8th, 9th, and 10th, the undermentioned Candidates were successful:—For *the Licence to Practise Medicine*—Thomas George Drake, Clonskeagh, Dublin; George Albert Dreaper, Castlecomer, Co. Kilkenny; Michael Edward Keating, Enniscorthy, Co. Wexford; Richard Murphy, Balbriggan, Co. Dublin; William Edmond O'Connor, Ferenure, Co. Dublin; Joseph Arthur Purdon, Belfast; John Robinson, Kilrathmurray, Co. Kildare; Frederick Joseph Wetherall Stoney, Cloughjordan. For the *Licence to Practise Midwifery*—Thomas George Drake; George Albert Dreaper; Michael Edward Keating; John E. McCraith, Smyrna, Asia Minor; Richard Murphy; Joseph Arthur Purdon; Frederick J. W. Stoney. The following candidate was examined and passed in the subjects of the First Professional Examination:—Frederick Mandel.

At a meeting of the President and Fellows, held on Friday, April 4th, 1884, the following were unanimously elected Honorary Fellows of the College:—Henry W. Acland, M.D. Oxon, C.B., Regius Professor of Physic in the University of Oxford, and President of the General Medical Council; Thomas Crawford, M.D. Edin., Director-General of the Army Medical Department. On the same occasion, the undermentioned Licentiate in Medicine and Member of the College was elected a Fellow:—William Josiah Smyley, M.D. Dub., Gynæcologist to the City of Dublin Hospital.

Royal Medical Benevolent College.—A third Perpetual Presentation to the Royal Asylum of St. Anne's Society, in favour of the orphan daughters of medical men, has been established by Mr. J. F. France, the right of nomination being vested in the members of the Council of the Royal Medical Benevolent College, who will immediately proceed to fill it up. Application should be made to the Secretary, at the office of the College in Soho Square.

Naval Medical Department.—The following appointments are announced:—Staff-Surgeon—William H. Stewart, to the *President*, additional, for temporary service at Victoria Yard. Surgeons—James Porter, to the *Alexandra*, additional, for service with the Marine battalion (appointment in lieu of Street, to the *Euryalus*, additional for such duty); John Wilson, M.D., to Sheerness Dockyard, *vice* Lynch, to the Malta Hospital; James B. Clibborn, to the Plymouth Hospital, *vice* Wilson; W. G. Jack, to the *Lord Warden*, *vice* Lennox. Inspector-General of Hospitals and Fleets, James N. Dick, has reported at the Admiralty his arrival in England, from Malta, on promotion.

Dermoid Cyst suspected from Microscopical Examination of the Urine.—The patient was a female, aged about 50. Every two, three, or four weeks she had, for many years, passed an enormous quantity of whitish lumps with her urine, suffering at the same time from excruciating pains. This urine appeared "flocky," and presented a glassy shining appearance. Under the microscope it proved to be composed almost entirely of horny epidermal substance, with a comparatively large number of crystals of sodic urate in the form of sheaves. Its composition, taken in conjunction with the symptoms, was believed to indicate the existence of a dermoid cyst, which, from time to time, discharged its contents into the pelvis of the kidney. With the exception of chronic laryngitis, and, at times, of hæmorrhoids, the patient was otherwise in good health.—*New York Medical Journal*, January 12th.

St. John Ambulance Association.—With the concurrence of the Principal Medical Officer, Devonport Garrison, classes for the troops have recently been held in connection with the St. John Ambulance Association, attended by officers, non-commissioned officers, and men of all ranks. Surgeon W. B. Allin, M.B., A.M.D., acted as lecturer, and Surgeon-Major Alex. Turner, A.M.D, as examiner. The latter has forwarded to St. John's Gate a most eulogistic report on the excellence of the knowledge displayed,

especially as regards practical work, and the first treatment of the wounded. This is shown by the fact that the whole of the candidates for examination, which took place in the presence of the Principal Medical Officer, are recommended for certificates, the members being as follows:—Royal Marines, 6; 2nd Batt. South Lancashire Regt. 22; 2nd Batt. Highland Light Infantry, 34; and Commissariat and Transport Corps, 12. Among the officers are Lieut.-Colonel S. J. Graham, C.B; Major H. J. L. Norcock; Captain R. H. Hall; Lieut. E. A. Snow, and Assistant-Commissary-General J. A. Scott.

Sir Patrick Dun's Hospital, Dublin.—The number of in-patients admitted last year was 1,262, and of out-patients treated 5,626. During the last five years 7,850 accident cases have been treated. The average daily expense of each patient during 1883 was, food, 12·1 pence; medicine and appliances, 2·5 pence; stimulants, 0·8 pence.

Glasgow Dispensary for Skin Diseases. — The annual meeting of this charity was held on the 9th instant. The medical report showed that during the past year 1,208 new cases were treated, of which 90 of the most serious were transferred and treated in special wards in the Western Infirmary. Since the opening of the dispensary in 1861 the total number treated amounted to 27,073. The financial statement showed that during the year the subscriptions collected were £268, and that the ordinary expenditure was £348; the debt on the house property had been reduced from £1,054 to £761.

Glasgow Royal Infirmary.—At a meeting of the directors of the Royal Infirmary, held on the 10th instant, it was resolved to increase the number of surgeons in the institution to six, owing to the large number of surgical wards, and to reduce the number of physicians to four. There are twelve medical wards, and this arrangement gives three wards to each physician.

Glasgow Hospital and Dispensary for Diseases of the Ear.—The annual meeting was held on the 9th instant. The report shows that the institution is in a most prosperous condition. During the past year 2,600 cases were treated, many of them being of a serious nature. After paying all expenses, a balance of 250*l.* remained in hand. An expression of regret was recorded, that owing to infirm health, Dr. Cassel's had been compelled to retire from the appointment of aural surgeon to the institution.

A Hospital for Newbury.—The scheme for establishing a hospital at Newbury, which has been instituted and earnestly pushed by Dr. Douglas, is now in a fair way towards realisation. Contributions amounting to upwards of 3,000*l.*, have been promised, and on Wednesday the 9th instant, Earl Carnarvon, who has accepted the office of President, presided over a large meeting, convened for the purpose of placing the proposal on a sound footing.

Netley Hospital.—On vacating the post of Governor and Commandant of the Royal Victoria Hospital, Sir C. Pearson issued an order in which he says:—"In taking leave officially of the officers, non-commissioned officers, and men belonging to and connected with this hospital, he begs to assure them that he does so with sincere regret, and, he hopes, with feelings of mutual regard and esteem. To the heads of departments, past and present, and to all who have been associated with him in administering the affairs of the station, Sir Charles Pearson desires to offer his warmest thanks for their assistance and friendly co-operation; nor can he part from the members of his own clerical staff without recording in this, his last Station Order, his sense of their uniform soldierly bearing and admirable conduct. That every success may attend the Army Medical Department, and that the future organisation of Netley Hospital may be of benefit alike to the army and to the medical service, is the earnest wish of their very sincere friend, its last Governor and Commandant."

Hospital Nomenclature.—The Metropolitan Asylums Board has forwarded circular communications to the various local bodies of the metropolis, informing them that in future the board's hospital at Hampstead will be known as the North-Western Hospital, that at Fulham as the Western, that at Stockwell as the South-Western, that at Deptford as the South-Eastern, that at Homerton as the Eastern, and that the proposed hospital at Winchmore-hill will be known as the Northern Hospital.

The Blind, Deaf-Mutes, and Idiots in Italy.—The *Annali Universali di Medicina* for March publishes a long statistical report on the distribution of blindness, deaf-dumbness, idiocy and cretinism in Italy. We have only space for the general results. At the census of 1881, the population numbered 28,495,628 (14,365,383 males and 14,194,245 females). Of these there were returned 21,718 (12,147 males and 9,571 females) as *blind*, viz., 76 per 100,000 (85 males to 67 females). The *deaf-mutes* amounted to 15,300 (8,707 males and 6,593 females) in number, or 54 per 100,000 (61 males to 46 females). Of idiots and cretins there were 19,671 (11,573 males and 8,098 females) or 69 per 100,000 (81 males to 57 females). Thus, in all these conditions the male sex largely predominates. In blindness and deaf-mutism the numbers have decreased as compared with the two preceding censuses; and with respect to deaf-mutism the dimunition has been constant and very great. The number of idiots and cretins have, on the other hand, slightly increased as compared with the census of 1871.

Hydrophobia in Paris.—On depositing at the *Académie de Médecine* a copy of his *Rapport sur les cas de Rage Humaine qui se sont produits dans le Département de la Seine pendant les années* 1881-83, Dr. Dujardin-Beaumetz observed that it contained the analysis of the 34 cases of hydrophobia which have occurred in Paris during the three years in the following proportion, viz.:—21 in 1881, nine in 1882, and four in 1883. All means of treatment that had been tried had, as heretofore, proved useless; but the vigorous action of the police in regard to stray dogs had proved most effectual in diminishing the number of cases.—*Bullétin de l'Académie*, April 8th.

Alcoholism in St. Petersburg.—The *St. Petersburger Medicinische Wochenschrift*, of April 5, quotes from the Russian Medical Journals some interesting figures in respect to the number of cases of alcoholism in the St. Petersburg hospital. Thus Dr. Nikolajew furnishes the results observed at five of the largest civil hospitals during eight years (1877-82)—including under the title alcoholism, delirium tremens, periodical drunkenness, and acute and chronic alcoholism. The entire number of cases amounted to 5,396, with a mortality of 6·1 per cent, the maximum number of cases occurring between July and September of each year. The cases rose as high as 1,048 in 1877, and 1,092 in 1879 (the beginning and end of the Turkish war), and fell in 1881 to 590, to rise again in 1881 to 930. Dr. E. Bary deriving his material from the Marien-Magdalenen Hospital, furnishes a table of 1,652 cases which were treated therein during 30 years, most cases occurring during the warmest months of each year, the maximum month being August. This circumstance Dr. Bary explains by the gains of the working classes being greater in the summer, while during the light warm evenings they indulge in greater excesses. Great differences in the numbers of different years are accounted for by the variations in social and political circumstances.

The Bacillus of Typhoid Fever.—The Council of the Linnean Society of New South Wales are offering a prize of 100*l.* for the best original essay on the above subject. The author must confine himself to facts which he has himself observed under methods which are to be clearly explained. Each essay must be in English, must be distinguished by a "motto," accompanied by an envelope containing the author's name, and must be delivered at the Society's house, Phillip-street, Sydney, on or before December 31st, 1884.

Syphilis Returns from the Royal Navy Health Report for 1882.—Of this disease in the primary form, 1,941 cases were under treatment during the year 1882, and in the secondary form 775, the former being in the ratio of 44·64 per 1,000, and showing a decrease of 3·69 per 1,000 when compared with the preceding year; and the

latter in the ratio of 17·82 per 1,000, and being an increase equal to ·55 per 1,000. On the Home Stations, it is to be gathered from the returns, there was a decrease of primary syphilis amounting to 2·28 per 1,000. On the Mediterranean, a decrease of 22·95 per 1,000; on the North America and West Indies, an increase of 16·08 per 1,000; on the South-east Coast of America, a decrease of 17·38 per 1,000; on the Pacific, an increase of 13·01 per 1,000; on the West Coast of Africa and Cape of Good Hope, an increase of 6·04 per 1,000; on the East India, an increase of 2·81 per 1·000; on the China Station, a decrease of 7·02 per 1,000; on the Australia Station, a decrease of 2·5 per 1,000; and in the Irregular Force, an increase of 3·22 per 1,000. Twenty-two persons were invalided for primary, and fifty-four for secondary, syphilis, during the year under notice.

Cremation.—A model of the crematorium used for the first cremations in England in modern times has recently been added to the Parkes Museum of Hygiene. The Council of the Parkes Museum propose to organise a representative collection of models of drawing apparatus used for cremation during the coming summer. Any persons willing to lend such models are requested to communicate with the Secretary at the Museum, Margaret Street, W.

Presentation to Mr. Hird, F.R.C.S.—A numerous gathering of friends, colleagues, and former pupils of Mr. Francis Hird, F.R.C.S., took place on Tuesday, week at Charing Cross Hospital Medical School, on the occasion of a presentation to him of a testimonial upon his retirement from the office of Dean, in recognition of his valuable services to the Medical School, extending over a period of forty-five years. Professor Huxley, P.R.S., presided, supported by Sir Joseph Fayrer, and Sir Guyer Hunter, all of whom were former pupils of Mr. Hird, at Charing Cross Hospital. The testimonial consisted of a service of plate, and an illuminated address on vellum.

The Distribution of Bacteria in Water.—The much-discussed question, says *Nature*, as to the purification of water in rivers "by itself"—that is, by the mere fact of its motion—seems to have entered into a new phase. Dr. Pehl, at St. Petersburg, has recently made a series of bacterioscopic measurements on the waters of the capital, which are summed up in the last issue of the *Journal of the Russian Chemical Society*. The water of the Neva itself appears to be very poor in bacteria, namely, 300 germs in a cubic centimetre. After heavy rains this number rises to 4,500, and to 6,500 during the thawing of the river. The canals of St. Petersburg, on the contrary, are infected with bacteria, their number reaching 110,000 in a cubic centimetre, even during good weather. The same is true with regard to the conduits of water for the supply of the city. While its chemical composition hardly differs from that of the Neva (by which they are supplied), the number of bacteria reaches 70,000, against 300 in the water freely taken from the river; and the worst water was found in the chief conduit, although all details of its construction are the same as in the secondary conduits. Dr. Pehl explains this anomaly by the rapidity of the motion of water, and he has made direct experiments in order to ascertain that. In fact, when water was brought into rapid motion for an hour, by means of a centrifugal machine, the number of developing germs was reduced by 90 per cent. Further experiments will show if this destruction of germs is due to the motion of the mass of water, or to molecular motion. The germs, among which Dr. Pehl distinguishes eight species, are not killed by immersion into snow. As the snow begins to fall, it brings down a great number of germs, which number rapidly diminishes (from 312 to 52 after a three hours' fall of snow, on January 21st, 1884), while their number on the surface of the snow increases, perhaps in consequence of the evaporation of snow, or of the condensation of vapour on its surface.

Mortality in Russia.—The paucity of medical men in Russia, and the habits of the rural population combine to make the Russian death-rate the highest in Europe. Excepting the two capitals, where there are many German physicians, there is no district in the empire sufficiently supplied with doctors. According to the latest returns the average duration of life in Russia is only 26 years. The mortality among infants is frightful. More than 60 per cent. die before they reach their fifth year. Nearly 2,000,000 children perish every year. Of 8,000,000 boys only 3,770,000 attain the age of military service, that is to say, their 25th year; and of these at least 1,000,000 are found, by reason of shortness of stature and weakness of body, unfit for military duties.

APPOINTMENTS.

Ashmead, George, L.R.C.P. Edin., L.R.C.S. Edin.—Medical Officer to the Kingswinford No. 4 District, Stourbridge Union.

Babst, Charles T. U.—Medical Officer to the Howden District, Auckland Union.

Hunt, G. A., L.R.C.P. Edin., M.R.C.S. Eng.—Medical Officer to the South Hornsey District, Edmonton Union.

Mason, A., L.R.C.S. Ire., B.M. Dub.—Assistant Resident Medical Officer to the Workhouse, Chorlton Union.

Matthews, Arthur, M.R.C.S. Eng., L.S.A.—Medical Officer to the Cleaton District, Whitehaven Union.

McLauchlan, T. G., M.B., C.M., Edin.—Medical Officer to the Halesowen District, Stourbridge Union.

Pritchard, S. E., L.R.C.P. Lond., L.S.A.—Medical Officer to the First District, St. George-in-the-East Parish.

Pughe, T. W. O., M.B., M.R.C.S.—Honorary Medical Officer to the Liverpool North Dispensary.

Westby, George, M.K.Q.C.P.I., &c.—Honorary Assistant Surgeon to the Liverpool Hospital for Cancer and Skin Diseases.

Wholey, T., L.R.C.P., M.R.C.S.—Resident Accoucheur to the London Hospital.

VACANCIES.

Birmingham General Hospital.—Resident Surgical Officer, &c. (*For particulars see Advertisement.*)

Cheshire County Asylum, Parkside, Macclesfield.—Medical Superintendent. Salary, £500 per annum, with furnished house, &c. Candidates must be duly qualified and registered Medical Practitioners. Full particulars can be obtained on application. Applications and testimonials, with 30 printed copies of the latter for circulation among the committee, to be sent to Mr. A. C. Procter, on or before May 3rd.

Gateshead Union.—Medical Officer for the East District, in succession to Mr. Douglas, resigned. Area, 1,060 acres. Salary, £50 per annum.

Liverpool Infirmary for Children, Myrtle Street.—House Surgeon. Salary, £85 per annum, with board and lodging. Applications, with testimonials, to be sent on or before April 19th.

Okehampton Union.—Medical Officer for the North Tawton District, in succession to Mr. Norman, resigned. Area, 24,560 acres. Population, 4,050. Salary, £62 10s. per annum.

Parochial Board of Kirkcowan.—Qualified Medical Practitioner. Salary, £52 per annum. Unmarried candidates preferred. Applications, with testimonials, to be sent to Peter Gordon, Inspector of Poor, on or before May 1st.

West End Hospital, 73, Welbeck Street, London, W.—Out-Patient Department Physician. Applications, enclosing not more than three recent testimonials, to be sent to the Secretary before April 21st.

DEATHS.

Bond, Harman Reed, Surgeon-Major, retired, Bengal Army, at Teignmouth, on April 7th, in his 73rd year.

Joseph, Thomas Morgan, M.R.C.S., L.R.C.P., late of Gladisville, near Sydney, Australia, on April 3rd, in his 41st year.

NOTES, QUERIES, AND REPLIES.

THE HIND FUND.

The following additional subscriptions have been received and paid to the account of the "Hind Fund" at Messrs. Coutts' Bank:—Dr. Clement Godson, £2 2s.; H. Royes Bell, Esq., £1 1s.; Dr. Cooper Crawford, £1 1s.; R. Maitland Coffin, Esq., £1 1s; John Deane, Esq., £1 1s.; T. F. Gandar, Esq., £1 1s.; T. Lawrence Read, Esq., £1 1s.; Dr. Henry J. Strong, £1 1s.; W. Baylie, Esq., 10s.; W. Jeyn, Esq., 5s. The fund is now closed.

University of Edinburgh.—The following congratulatory address of the Royal College of Surgeons of England was presented on the 17th instant to the above University, viz.:—"The President, Vice-President, and Council of the Royal College of Surgeons of England hereby offer their warmest congratulations to the University of Edinburgh, on its attaining the three hundreth year of its existence. They avail themselves of this auspicious occasion to acknowledge the great public benefits rendered in the past by

this ancient University in the promotion of education, the encouragement of learning, and the cultivation of science. They desire especially to accentuate their acknowledgment of the prominent position held by the University in whatever relates to the accumulation and diffusion of medical and surgical knowledge. They trust that in the centuries to come, the University of Edinburgh may, with other like institutions, long pursue its honourable career, and fulfil its high destiny."

C. J. Egan, Esq., King William's Town, South Africa.—Letter and enclosure received with thanks.

Dr. John Drysdale, Port Chalmers, Opago, New Zealand.—Letter and enclosure received with thanks.

COMMUNICATIONS RECEIVED—

The Editor, Sanitary Engineer, New York; The Registrar-General, Edinburgh; Sir Edmund Lechmere, London; The Editor, British Medical Journal, London; The Secretary, Apothecaries' Society, London; Dr. Ewart, London; Dr. Williams, Llandudno; Dr. Larmuth, Hackney; Dr. Jones, New Orleans; Dr. J. H. Clarke, London; Dr. J. B. Jardine, Chatham; Mr. Ruspini, Knutsford; Dr. George Harley, F.R.S., London; Mr. Edmund Gurney, London; Mr. Taneyhill, Baltimore; Dr. Fowler, London; The Editor, The Schoolmaster; Mr. T. M. Stone, London; The Hon. Secretary, Hunterian Society, London; Dr. Willoughby, London; Dr. Hughes Bennett, London; Mr. Robert Freeman, London; Mr. J. R. Forrest, Herne Hill; The Secretary, Royal Institution, London; The Secretary, Royal Medical and Chirurgical Society, London; The Hon. Secretary, Clinical Society, London; Dr. Norman Kerr, London; The Secretary, Medical Faculty, University of Aberdeen; Dr. Domett Stone, London; Dr. J. W. Moore, Dublin; Messrs. G. Street & Co., London; The Hon. Director, Anthropological Institute of Great Britain and Ireland, Dr. Sturges.

BOOKS RECEIVED—

Die Diphtheritis und ihre Behandlung, von Dr. Hübener—Epidemics, by G. Waters—Transactions of the Medical Association of the State of Missouri—Contagious and Infectious Diseases Measures, by J. Jones, M.D.—Annual Report of the Wilts County Asylum for 1883—Clinical Aspects of Cerebral Syphilis, by H. C. Wood, M.D.—The Utility and Morality of Vivisection, by G. Gore, LL.D., F.R.S.—Address, by W. T. Gairdner, M.D., LL.D.—Anatomy of the Inguinal and Femoral Regions, by Edward L'E. Ledwich—Corpulence and its Treatment, by Dr. Wilhelm Ebstein—Year-book of Therapeutics, by R. W. Amidon, M.D.—Year-book of Surgery, by C. H. Knight, M.D.—Annual Report of the Staffordshire County Lunatic Asylum for 1883—Report, &c., of the Port of London Sanitary Committee—Opinions of the Press on the London Municipal Government.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Revista de Medicina—Bulletin de l'Académie de Médecine—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Revue Médicale—Gazette Hebdomadaire—Nature—Boston Medical and Surgical Journal—Louisville Medical News—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt fur Klinische Medicin—Philadelphia Medical News—Le Progrès Médical—New York Medical Record—The Journal and Hospital Gazette—New York Medical Journal—Students' Edinburgh Clinical and Pathological Journal—The Philadelphia Medical Times—Centralblatt für die Medicinischen Wissenschaften—Berliner Klinische Wochenschrift—The Planet—Weekblad—Maryland Medical Journal—The Glasgow Medical Journal—Medical Annals of Baltimore—The Journal of Anatomy and Physiology—The Australian Medical Gazette—Revue des Sciences Médicales—Bulletins et Mémoirs—The Southern Clinic—The Hampshire County Advertiser, April 9th—The Essex Telegraph, April 12th—Revue de Médecine—Revue de Chirurgie—The Journal of Nervous and Mental Diseases—The Journal of the Vigilance Association—The Canada Lancet—The Dublin Journal of Medical Science—The Journal of the British Dental Association—The Canadian Practitioner—The Practical Confectioner.

APPOINTMENTS FOR THE WEEK.

April 19. *Saturday* (*this day*).

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

21. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Medical Society of London.—Dr. Whipham, on "Suppurative Disease of the Stomach;" Dr. Joseph Ewart (Brighton), on "The Treatment of Simple and Sloughing Dysentery by large doses of Ipecacuanha, given morning and evening only." At 8 p.m. Mr. J. Sampson Gamgee (Birmingham) will show "A New Sponge to abolish Sponge Infection."

22. *Tuesday.*

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Anthropological Institute of Great Britain and Ireland, 8 p.m.—First Meeting in the New Rooms, at No. 3, Hanover Square. The following will be the order of business:—The Marquis of Lorne, K.T., G.C.M.G., &c., "Exhibition of a Collection of Ethnological Objects from Canada;" Sir Reginald Owen, K.C.B., F.R.S., "Note on a Portrait of an Aboriginal Tasmanian;" Prof. A. H. Keane, B.A., on "The Ethnology of the Sudan." The Chair will be taken by Prof. Flower, LL.D., F.R.S.

Royal Institution, 3 p.m.—Dr. Klein, "Nerve and Muscle."

Royal Medical and Chirurgical Society, 8.30 p.m.—Mr. F. B. Jessett, "An Enquiry into the Cause of the Increase of Cancer in England and Wales;" Mr. C. Macnamara, "Epiphysitis;" Mr. F. J. Gant, "A Pelvic and Parietal Tumour of the Abdomen; Removal by Operation and Recovery."

23. *Wednesday.*
